

# **Reaktivität und Selektivität anellierter, verbrückter und tertiärer Sauerstoff-Radikale**

---

Vom Fachbereich Chemie der Universität Kaiserslautern  
zur Verleihung des akademischen Grades  
„Doktor der Naturwissenschaften“  
genehmigte Dissertation

**D386**

Tag der wissenschaftlichen Aussprache: 10.07.2015

Prüfungsvorsitzender: Prof. Dr. Markus Gerhards

Erstgutachter und Betreuer: Prof. Dr.-Ing. Jens Hartung

Zweitgutachter: Prof. Dr. Stefan Kubik

vorgelegt von

Diplom-Chemikerin **Christine Schur**

Kaiserslautern 2015

***Für meine Eltern,  
meine drei coolen Schwestern  
und natürlich meinen Schatz!!!***

Die vorliegende Arbeit wurde in der Zeit von Februar 2009 bis Mai 2015 im Fachbereich Chemie (Organische Chemie) der Technischen Universität Kaiserslautern durchgeführt.

Herrn Prof. Dr.-Ing. Jens Hartung danke ich, neben der Aufnahme in seinen Arbeitskreis, für die Bereitstellung meines Promotionsthemas.

Für das Zweitgutachten danke ich Prof. Dr. Stefan Kubik und für den Vorsitz der Prüfungskommission Prof. Dr. Markus Gerhards.

Dr. Harald Kelm danke ich für die bereitwillige Übernahme der Protokollführung.

Prüfungskommission:

Vorsitzender: Prof. Dr. Markus Gerhards

Erstgutachter: Prof. Dr.-Ing. Jens Hartung

Zweitgutachter: Prof. Dr. Stefan Kubik

Die Ergebnisse der vorliegenden Dissertation wurden in den folgenden begutachteten Arbeiten veröffentlicht oder sind zur Veröffentlichung vorgesehen.

## Eidesstattliche Erklärung

Hiermit erkläre ich ehrenwörtlich, dass ich die vorliegende Arbeit selbständig angefertigt und keine anderen als die angegebenen Quellen und Hilfsmittel benutzt habe.

Ich erkläre außerdem, dass diese Dissertation weder in gleicher noch in ähnlicher Form bereits in einem anderen Prüfungsverfahren vorgelegen hat und ich, außer den mit dem Zulassungsgesuch urkundlich vorgelegten Graden, keine weiteren akademischen Grade erworben habe oder zu erwerben versucht habe.

Kaiserslautern, den 19.05.2015

---

Christine Schur

## Erläuterungen

Die vorliegende Arbeit besteht aus einer Zusammenfassung, einer Einleitung (Kapitel 1), einem Kenntnisstand mit Aufgabenstellung (Kapitel 2), drei voneinander unabhängigen Ergebnisteilen (Kapitel 3–5), sowie einem Anhang. Forschungsartikel sind jedem Kapitel als Unterpunkt beigelegt, wobei dazugehörige Zusatzinformationen (*Supporting Information*), wie experimentelle Daten, Methoden, verwendete Arbeits- und Messgeräte im Anhang zu finden sind. Für jedes Kapitel wurde ein separates Literaturverzeichnis erstellt, wobei mehrfach zitierte Referenzen in jedem Kapitel neu berücksichtigt wurden.

Abbildungen, Tabellen und Schemata sind im jeweiligen Kapitel fortlaufend nummeriert. Die Nummerierung der Strukturformeln in den Ergebnisteilen beginnt stets neu und stimmt nicht zwingend mit der Nummerierung in den Forschungsartikeln überein. Strukturformeln mit Keilschreibweise bezeichnen, wenn nicht anders angegeben, relative und nicht absolute Konfigurationen.

Die Hierarchie von Substituenten zur Benennung von Verbindungen folgt in einigen Fällen nicht der IUPAC-Hierarchie, falls inhaltliche Zusammenhänge innerhalb homologer Reihen durch alternative Molekülnamen didaktisch einfacher nachvollziehbar werden.

## Zusammenfassung

In der vorliegenden Arbeit wurde die Reaktivität und Selektivität anellierter, verbrückter und tertiärer *O*-Radikale, in drei Teilprojekten, untersucht. Die zur Erzeugung primärer und sekundärer *O*-Radikale benötigten Thiohydroxamsäure-*O*-ester stammen aus Reaktionen von Cyclopentenyltosylaten mit 3-Hydroxy-4-methylthiazol-2(3*H*)-thion-Tetraethylammoniumsalz (Salz-Methode). Für tertiäre Thiohydroxamsäure-*O*-ester hat sich die Umsetzung tertiärer *O*-Alkylisoharnstoffe mit 3-Hydroxy-4-methylthiazol-2(3*H*)-thionen bewährt (Isoharnstoff-Methode). Die anschließende Freisetzung der *O*-Radikale, aus den *O*-Alkylthiohydroxamaten, erfolgte photochemisch oder thermisch unter pH-neutralen und nicht oxidativen Bedingungen in Gegenwart von Bromtrichlormethan. Relative Reaktivitäten der *O*-Radikale in Sauerstoff-Elementarreaktionen beruhen auf Abschätzungen mit Hilfe unimolekularer Vergleichsreaktionen (*Radikaluhr Konzept*). Beobachtete Selektivitäten und Stabilitäten wurden anhand theoretischer Analyseverfahren (Twist-Modell, Dichtefunktional-Rechnungen und Møller-Plesset-Störungsrechnung 2. Ordnung), in Kooperation mit Jens Hartung, interpretiert und quantifiziert. Die synthetisierten  $\beta$ -bromierten, bicyclischen, tricyclischen sowie tertiären Tetrahydrofurane erweitern die bis dato auf primäre und sekundäre Monocyclen beschränkte Vielfalt der 5-Ring-Strukturen über Sauerstoff-Radikalreaktionen. Beispiele für Synthesen mittels intermolekularer *O*-Radikaladditionen liefern funktionalisierte Bromalkoxybicyclo[2.2.1]heptane und *tert*-Butoxybromalkane.

Durch Variation (1,2-Cyclopentyl und 1,2-Cyclohexyl) und Permutation (Kohlenstoff-Atome C1 und C2 / C2 und C3 / C3 und C4) der Anellierung, sowie durch verbrückte Reste (C2 und C5 / C3 und C5) am 4-Penten-1-oxyl-Gerüst gelang es, im ersten Teilprojekt, diastereomerenreine primäre und sekundäre *O*-Radikalvorläufer für eine systematische Untersuchung der Stereoselektivität in 5-*exo-trig*-Reaktionen zu synthetisieren. Umsetzungen der *O*-Radikalvorläufer zeigten Regelmäßigkeiten im Produktbild, die in Form von Richtlinien für zukünftige Synthesepanungen zusammengefasst wurden: (I) Für sterisch und elektronisch vergleichbare Substituenten in direkter Nachbarschaft (zum Beispiel C1 und C2) ist der stereochemische Einfluss des Substituenten größer, der der Doppelbindung näher ist (hier Substituent an C2). Die relative Konfiguration der beiden anellierten Substituenten zueinander wirkt sich auf den Stereoselektivitätsgrad aus, wobei *trans*-anellierte 4-Penten-1-oxyl-Radikale stereoselektiver cyclisieren als *cis*-konfigurierte Isomere. Hauptprodukte der 1,2- und 2,3-cyclohexyl-anellierten 4-Penten-1-oxyl-Radikale sind 2,4-*cis*- und 2,3-*trans*-

substituierte Tetrahydrofurane. (II) Ist die Flexibilität der Sauerstoffatom-tragenden Seitenkette konformell eingeschränkt, cyclisieren anellierte (C3 und C4) sowie verbrückte (C2 und C5 / C3 und C5) 4-Penten-1-oxyl-Radikale 2,3- und 2,4-*cis*-spezifisch an *endo*- und *exo*-cyclische  $\pi$ -Bindungen. Theoretische Berechnungen diesbezüglich haben gezeigt, dass der 2,3-*trans*-Ringschluss des Modell-Radikals 1-(Cyclohexen-3-yl)-2-ethoxylradikal aufgrund sterischer Effekte eine deutlich höhere Barriere besitzt (89.5 kJ/mol) als der 2,3-*cis*-Ringschluss (35.4 kJ/mol).

Die Herstellung tertiärer 3-Alkyloxy- und 3-Cumyloxy-5-(4-methoxyphenyl)thiazol-2(3*H*)-thione und die Untersuchung der Reaktivitäten daraus erzeugter tertiärer *O*-Radikale in Elementarreaktionen waren Schwerpunkte des zweiten Themengebiets. Experimentell bestimmte relative Geschwindigkeitskonstanten für die  $\delta$ -H-Abstraktion ( $k^{\text{Subst}} = 10^7\text{--}10^8 \text{ s}^{-1}$ ), die 5-*exo-trig*-Cyclisierung ( $k^{5\text{-exo}} = 10^8\text{--}10^9 \text{ s}^{-1}$ ) und die intermolekulare Addition ( $k^{\text{Add}} = 10^7 \text{ M}^{-1}\text{s}^{-1}$ ) demonstrieren, dass tertiäre *O*-Radikale trotz größerer sterischer Hinderung eine ähnliche (Substitution) oder höhere Reaktivität (5-*exo*-Reaktion) als vergleichbare primäre und sekundäre Analoga aufweisen. Der 5-*exo*-Ringschluss des 2-Phenyl-5-hexen-2-oxyl-Radikals erfolgt 2,5-*cis*-selektiv. Intermolekulare Additionen der *tert*-Butoxyl-, Cumyloxyl- oder *p*-Chlorcumyloxyl-Radikale an Norbornen verlaufen *exo*-spezifisch. Dichtefunktional Berechnungen zufolge sind Torsionsspannungen im 2,5-*trans*-Übergangszustand der 5-*exo-trig*-Cyclisierung und im *endo*-Übergangszustand der intermolekularen Addition für die beobachtete Selektivität verantwortlich.

Im dritten Projekt wurden *O*-(*tert*-Butyl)thiohydroxamate aus *O*-(*tert*-Butyl)-*N,N*-diisopropylisoharnstoff und dem 3-Hydroxy-4-methylthiazol-2(3*H*)-thion sowie dem 3-Hydroxy-4-methyl-5-(4-nitrophenyl)thiazol-2(3*H*)-thion hergestellt. Die gleiche Reaktion zeigt bei Verwendung des 1-Hydroxypyridin-2(1*H*)-thions eine spontane Umlagerung des *O*-(*tert*-Butyl)thiohydroxamats zum *O*-(*tert*-Butyl)pyridin-2-sulfonat. Stabilitätsunterschiede der tertiären Thiohydroxamat-Klassen lassen sich der Molekülorbital-Theorie folgend auf drei unterschiedliche,  $\pi$ -artige Wechselwirkungen der N,O-Bindung mit dem Thiohydroxamat-Kern und dem *O*-Alkyl-Rest im Grundzustand zurückführen, die die N,O-Bindung insgesamt stärken. Tertiäre 3-Alkoxythiazolthione erfahren dabei eine größere Stabilisierung als vergleichbare Pyridinthione. Photochemische Umsetzungen der *tert*-Butoxythiazolthione liefern *tert*-Butoxyl-Radikale, die durch Addition an 5,5-Dimethylpyrrolidin *N*-Oxid (DMPO) und Styrol nachgewiesen wurden.

# 1. Einleitung

## 1.1 Struktur und Reaktivität sauerstoffzentrierter Radikale

Als reaktive Zwischenstufen<sup>[1]</sup> organischer Synthesen weisen Sauerstoff-Radikale eine zwei bis drei Größenordnungen höhere Reaktivität auf als vergleichbare Kohlenstoff-Radikale.<sup>[2,3]</sup> In atmosphärischen<sup>[4,5]</sup> und biochemischen Prozessen<sup>[6-9]</sup> spielen O-Radikale eine wichtige Rolle bei Abbaureaktionen und zur Knüpfung von C,O-Bindungen.<sup>[10-12]</sup> Außergewöhnlich hohe Selektivitäten bei Additionen an Mehrfachbindungen<sup>[10,13-15]</sup>, H-Abstraktionen<sup>[16-17]</sup>,  $\beta$ -C,C-Fragmentierungen<sup>[18-19]</sup> oder Umlagerungsreaktionen<sup>[20-21]</sup> tragen dazu bei, dass O-Radikalreaktionen zunehmend an Bedeutung gewinnen. Mechanistische Untersuchungen der vergangenen Jahre haben gezeigt, dass die Reaktivität und Selektivität von Sauerstoff-Radikalen maßgeblich durch den Substituenten R beeinflusst wird (Abb. 1.1).<sup>[22]</sup>

**Abbildung 1.1.** Struktur und Reaktivität sauerstoffzentrierter Radikale.<sup>[22]</sup>

Sauerstoff-Radikalreaktionen sind im Allgemeinen stark exotherme Prozesse mit hohen Aktivierungsenergien für Rückreaktionen. Additionen, H-Abstraktionen und Umlagerungen verlaufen kinetisch kontrolliert unter Bildung starker C,O- bzw. O,H-Bindungen. Für Fragmentierungen ist die Energiedifferenz der Aktivierungsbarrieren zwischen Hin- und Rückreaktion deutlich kleiner. Rückreaktionen werden experimentell dennoch selten beobachtet, da der anschließende Radikaleinfang durch Wasserstoffatom- oder Halogenatom-Donoren meist deutlich schneller erfolgt (Schema 1.1).<sup>[22]</sup>

**Schema 1.1.** Elementarreaktionen sauerstoffzentrierter Radikale mit charakteristischen Geschwindigkeitskonstanten. R = H, Alkyl, Aryl.<sup>[23–26]</sup>

Die hohe Reaktivität und die ausgeprägte thermochemische Triebkraft von Sauerstoff-Radikalen bildet sich dem Hammond-Postulat<sup>[27]</sup> folgend in der Position von Übergangszuständen auf den dazugehörigen Reaktionskoordinaten ab. Geometrien früher Übergangszustände ähneln dabei strukturell den Startmaterialien, so dass deren Grenzorbitale zur Beschreibung von Reaktivitäten und Selektivitäten herangezogen werden können.<sup>[28,29,30]</sup> Günstige Wechselwirkungen ergeben sich dabei zwischen dem höchsten besetzten Orbital (HOMO, *engl.* Highest Occupied Molecular Orbital) eines nukleophilen oder dem tiefsten unbesetzten Orbital (LUMO, *engl.* Lowest Unoccupied Molecular Orbital) eines elektrophilen Reaktionspartners mit dem einfach besetzten Orbital (SOMO, *engl.* Singly Occupied Molecular Orbital) des O-Radikals. Je ähnlicher die Energien der wechselwirkenden Grenzorbitale sind, desto stärker ist nach dem Klopman-Theorem die Stabilisierung des Ensembles. In den meisten Reaktionen zeigen O-Radikale überwiegend elektrophile Reaktivität, das heißt die SOMO/HOMO-Wechselwirkung ist effektiver als die SOMO/LUMO-Wechselwirkung (Abb. 1.2, rechts). Bei Additionen an Alkene, die mit starken Akzeptorgruppen substituiert sind, reagieren Sauerstoff-Radikale aber auch als Nukleophile. In diesem Fall dominiert die SOMO/LUMO-Wechselwirkung gegenüber der SOMO/HOMO-Wechselwirkung (Abb. 1.2, links).<sup>[31]</sup>

**Abbildung 1.2.** Grenzorbitalwechselwirkungen eines Akzeptor-substituierten Alkens (A = CO<sub>2</sub>Me, CN) mit einem nukleophilen *O*-Radikal (RO•, links) und eines Donor-substituierten Alkens (D = OCH<sub>3</sub>, CH<sub>3</sub>, Ph) mit einem elektrophilen *O*-Radikal (RO•, rechts). R = Alkyl, Aryl.<sup>[31]</sup>

## 1.2 Stereo- und Regioselektivitäten substituierter 4-Penten-1-oxyl-Radikale

Im Verlauf der letzten 20 Jahre zeichneten sich deutliche synthetische Fortschritte bei intramolekularen *O*-Radikaladditionen ab. 4-Penten-1-oxyl-Radikalcyclisierungen stellen in diesem Zusammenhang die wichtigste Gruppe dar.<sup>[10,15,22–24,32,33]</sup> Die in diesen Reaktionen entstehenden Tetrahydrofuranymethyl-Radikale lassen sich mit Wasserstoff- oder Halogenatomen zu präparativ nützlichen Syntheseprodukten abfangen (Schema 1.2).<sup>[24,34–36]</sup> Aufgrund elektrophiler Eigenschaften der Alkoxy-Radikale in Additionen an terminale oder Donor-substituierte  $\pi$ -Bindungen verlaufen *O*-Radikaladditionen häufig mit komplementärer Stereo- und Regioselektivität, im Vergleich zu Elektrophil-induzierten, ionischen 4-Pentenolcyclisierungen (nukleophiles Sauerstoffatom).<sup>[35,37,38]</sup> Der präparative Wert der *O*-Radikalcyclisierungen leitet sich, neben interessanten Chemoselektivitäten, aus vorhersagbaren Stereoselektivitäten ab.<sup>[24,32]</sup> Alkyl- und *ortho*-Methyl-substituierte Arylsubstituenten in Position 1 sowie Alkyl- und Arylsubstituenten in Position 3 dirigieren die 5-*exo-trig* Reaktion 2,5-*trans*-selektiv, während Alkyl- und Arylsubstituenten in Position 2 Produkte mit *cis*-Konfiguration favorisieren. Annähernd äquivalente *cis/trans*-Mischungen resultieren aus der Umsetzung von 4-Penten-1-oxyl-Radikalen mit *para*- oder unsubstituierten Phenylresten in Position 1.<sup>[39]</sup> Der stereochemische Einfluss von Steuergruppen in 5-*exo-trig*-Reaktionen steigt mit sinkendem Abstand zur  $\pi$ -Bindung. Terminale Methylgruppen beschleunigen durch einen polaren Effekt den Angriff eines elektrophilen *O*-Radikals und üben für Alkyl-

und Arylsubstituenten in den Positionen 1 und 3 einen Diastereoselektivitäts-steigernden Effekt aus (Schema 1.2).<sup>[24,32,36]</sup>

**Schema 1.2.** Diastereoselektivitäten bei der intramolekularen 5-*exo*-Addition substituierter 4-Penten-1-oxyl-Radikale in Gegenwart von  $\text{Bu}_3\text{SnH}$  (oben) und  $\text{BrCCl}_3$  (unten).<sup>[24, 35]</sup>

Die beobachteten Selektivitäten lassen sich mit einem stereochemischen Modell (Twist-Modell, Schema 1.3)<sup>[40]</sup> beschreiben. Es wurde mit dem Ziel entwickelt, Stereoselektivitäten experimentell nicht durchgeführter Reaktionen in Synthesepanungen vorherzusagen. Dem Twist-Modell zufolge greift das Sauerstoff-Radikal aus stereoelektronischen Gründen die  $\pi$ -Bindung orthogonal zur Alkenebene an. Die Vinyl-Gruppe und das Kohlenstoff-Atom C3 nehmen aus sterischen Gründen bevorzugt entgegengesetzte Positionen entlang der Ebene ein, die von den Atomen O1, C5 und C4 definiert wird. Substituenten im konformell flexiblen Teil sind, aufgrund sterischer Effekte (Torsionsspannungen), vorzugsweise äquatorial (C2, C3) oder *pseudo*-äquatorial (C4) angeordnet. Die Bildung von *cis*/*trans*-Isomeren resultiert aus einer  $180^\circ$ -Rotation der terminalen Vinyl-Gruppe um die C4-C5-Bindung.

**Schema 1.3.** Twist-Modell-Übergangsstrukturen zur Beschreibung von Stereoselektivitäten in 5-*exo*-Cyclisierungen substituierter 4-Penten-1-oxyl-Radikale.<sup>[40]</sup> Kugeln = Alkyl, Aryl.

4-Penten-1-oxyl-Radikalcyclisierungen verlaufen nicht nur stereoselektiv, sondern weisen zudem eine ausgeprägte Regioselektivität auf.<sup>[24,41]</sup> Radikale, die in Position 4 der 4-Penten-1-oxyl-Radikalkette ein Wasserstoffatom tragen, liefern ein charakteristisches 98:2-Verhältnis an 5-*exo* und 6-*endo*-Cyclisierungsprodukten. Entlang der Reihe der Substituenten Wasserstoff, Methyl, *tert*-Butyl und Phenyl in Position 4 steigt der Anteil an 6-*endo*-Cyclisierungsprodukt auf 7:93 (Abb. 1.3). Regioselektivitätsänderungen basieren auf einer Balance zwischen Grenzorbitalwechselwirkungen und Torsionsspannungen im Übergangszustand.<sup>[41]</sup>

**Abbildung 1.3.** 6-*endo-trig*-Übergangsstruktur substituierter 4-Penten-1-oxyl-Radikale. R = H, Methyl (*exo:endo* = 69:31), *tert*-Butyl (*exo:endo* = 46:54), Phenyl (*exo:endo* = 7:93).<sup>[41]</sup>

Mit der sich entwickelnden Vielfalt der bisher untersuchten 5-*exo*-Reaktionen ist die Zeit gekommen, Synthesen komplexerer Tetrahydrofuran-Naturstoffe, die aus substituierten Monocyclen oder aus Bi- und Tricyclen bestehen, durch Ringschlussreaktionen tertiärer und anellierter 4-Penten-1-oxyl-Radikale aufzubauen (Abb. 1.4). Dabei wäre zu hinterfragen, inwieweit stereochemische Richtlinien für die Synthese von Monocyclen (Twist-Modell) auf die Darstellung anspruchsvollerer Molekülstrukturen übertragen werden können und ob tertiäre 4-Penten-1-oxyl-Radikale überhaupt für derartige Synthesezwecke eingesetzt werden können. Mit diesen Fragestellungen beschäftigt sich die vorliegende Dissertation.

**Abbildung 1.4.** Tetrahydrofuran- und Tetrahydropyran-abgeleitete Naturstoffe mit tertiären Ether- und polycyclischen Grundgerüsten.<sup>[42–46]</sup>

## 2. Kenntnisstand und Aufgabenstellung

### 2.1 Erzeugung von *O*-Radikalen

Sauerstoff-Radikale entstehen durch homolytische Spaltung schwacher Bindungen, die aus einem Sauerstoff- und einem Heteroatom wie beispielsweise Chlor, Stickstoff, Sauerstoff oder Schwefel bestehen (Abb. 2.1).<sup>[1–17]</sup> Mechanistische und synthetische Studien profitieren dabei von pH-neutralen, nicht oxidativen Bedingungen zur Sauerstoff-Radikalerzeugung, da so unerwünschte Produkte aus Oxidationsprozessen ausbleiben. Für die anschließende *O*-Radikalreaktion sind unverzweigte Kettenreaktionen vorteilhaft, da diese es erlauben, stationäre und niedrige Radikalkonzentrationen aufrecht zu erhalten, in denen Radikal-Molekülreaktionen über Radikal-Radikalreaktionen dominieren (Schema 2.1).<sup>[18,19]</sup> Nach dem Quasistationaritätsprinzip von M. Bodenstein<sup>[20,21]</sup> liegen solche Bedingungen dann vor, wenn eine reaktive Zwischenstufe langsam gebildet und schnell umgesetzt wird, was sich experimentell durch einen Überschuss an Radikalabfangreagenzien realisieren lässt. In verzweigten Kettenreaktionen nimmt die Radikalkonzentration bei Umsetzung eines Stoffes stetig zu, so dass in der Regel große Mengen unerwünschter Nebenprodukte gebildet werden.<sup>[18,19]</sup>

**Abbildung 2.1.** Auswahl sauerstoffzentrierter Radikalvorläufer des letzten Jahrhunderts. R = R' = Alkyl, Aryl.<sup>[1–17]</sup>

Die Technik zur Erzeugung von *O*-Radikalen mit Hilfe unverzweigter Kettenreaktionen stammt aus den Jahren 1988–1997 (Abb. 2.1), in denen die cyclischen Thiohydroxamsäureester **1** und **2** für diese Zwecke entwickelt wurden. Mechanistisch entstehen *O*-Radikale ( $\text{RO}\cdot$ ) aus *O*-Alkylthiohydroxamaten durch homolytische Spaltung der schwachen N,O-Bindung. Ursache des N,O-Bindungsbruchs ist der Angriff des kettenträgenden Radikals  $\text{Y}\cdot$  am

Thiocarbonylschwefel (Schema 2.1). Das Radikal  $Y\bullet$  stammt aus einem Mediator  $X-Y$  und wird photochemisch (25 °C) ohne Radikalstarter oder thermisch (80 °C), unter Zuhilfenahme von Initiator-molekülen wie Azobis(isobutyronitril) (AIBN), erzeugt. Aus den Sauerstoff-Radikalen ( $RO\bullet$ ) entstehen, den Elementarreaktionen folgend, stabilere Kohlenstoff-Radikale ( $R\bullet$ ), die durch den Mediator  $X-Y$  unter Bildung des kettentragenden Radikals  $Y\bullet$  abgefangen werden. Für die Kettenfortsetzung ist entscheidend, dass  $Y\bullet$  schneller an den Thiocarbonylschwefel addiert als jedes andere an der Reaktion beteiligte Radikal. Geringe Radikalkonzentrationen ( $< 0.01$  M) verhindern einen vorzeitigen Kettenabbruch durch Disproportionierung oder Rekombination.<sup>[22,23]</sup>

**Schema 2.1.** Unverzweigte Kettenreaktion Thiohydroxamat-abgeleiteter *O*-Radikale.  $X-Y = BrCCl_3, CCl_4, IC_4F_9, Bu_3SnH, HSC_8H_9, HSi(SiMe_3)_3$ .  $R = \text{Alkyl, Alkenyl}$ .<sup>[22]</sup>

Als Mediatoren für Synthesen mit Sauerstoff-Radikalen eignen sich insbesondere Halogenatom-<sup>[24–27]</sup> oder Wasserstoffatom-<sup>[23,24]</sup>Donoren. Während letztere zu reduktiv terminierten Produkten führen, eignen sich erstere zur Funktionalisierung der Reaktionsprodukte für Folgereaktionen. Für die Auswahl des Mediators sind Toxizität, Funktionalisierung, aber auch die Geschwindigkeit des Radikaleinfangs ausschlaggebend. Als wirkungsvoller Mediator zur Bromierung von Radikalen hat sich Bromtrichlormethan ( $k^{Br} \sim 10^8 \text{ M}^{-1}\text{s}^{-1}$ ) bewährt.<sup>[26,27]</sup>

## 2.2 Herstellung und Reaktivität cyclischer Thiohydroxamsäure-*O*-ester

Aufgrund der günstigen Kombination aus präparativer Zugänglichkeit, Lagerstabilität und chemischer Reaktivität in unverzweigten Kettenreaktionen stellen 3-Alkoxythiazol-2(3*H*)-thione zur Zeit die vermutlich praktikabelsten Vorläufer zur Erzeugung von Sauerstoff-Radikalen unter „Zinn-freien“ sowie pH-neutralen, nicht-oxidativen Bedingungen in präpara-

tiven und mechanistischen Studien dar.<sup>[23–28]</sup> Primäre und sekundäre 3-Alkoxythiazol-2(3*H*)-thione können aus Alkoholen mit Hilfe des Mitsunobu-Verfahrens<sup>[29]</sup> oder aus Alkylhalogeniden und Alkyltosylaten durch nukleophile Substitution mit einem Thiohydroxamat-Salz (Salz-Methode, Schema 2.2)<sup>[30]</sup> dargestellt werden. Für sekundäre *O*-Alkylthiohydroxamate erfolgt die C,O-Bindungsknüpfung unter Inversion der Konfiguration.

**Schema 2.2.** Synthese eines Thiohydroxamsäure-*O*-esters aus dem 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazol-2(3*H*)-thion (An = Anisyl) über das Tetraethylammonium-Salz der Thiohydroxamsäure und einem Alkyltosylat in einer S<sub>N</sub>2-Reaktion (Salz-Methode).<sup>[30]</sup>

Tertiäre Thiohydroxamsäure-*O*-ester können aus *O*-Alkylisoharnstoffen<sup>[29,30]</sup> (Isoharnstoff-Methode) und Thiohydroxamsäuren hergestellt werden, wobei die Synthese dieser Verbindungen bislang nur in Ansätzen untersucht ist (Schema 2.3).<sup>[9,33,34]</sup>

**Schema 2.3.** *O*-Alkylierung des 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazol-2(3*H*)-thions mit *tert*-Butanol, Diisopropylcarbodiimid (DIC) und katalytischen Mengen Cu(I)Cl.<sup>[33,34]</sup>

Das größte Anwendungsgebiet primärer und sekundärer 3-Alkoxythiazol-2(3*H*)-thione als Vorläufer von Sauerstoff-Radikalen liegt in der stereoselektiven Synthese monocyclischer Tetrahydrofurane.<sup>[23,26–28,30,35,36]</sup> Zu Beginn dieser Arbeit existierten kaum Ergebnisse zum Aufbau bi-, tri- oder polycyclischer Ether über dem Sauerstoff-Radikale. Eine Erweiterung des

Sauerstoff-Radikal-Verfahrens um die genannten Stoffklassen würde die Synthesechemie durch das Erschließen neuer Grundstrukturen bereichern.

**Schema 2.4.** Intermolekulare Addition des *tert*-Butoxyl-Radikals an Norbornen.<sup>[37]</sup>

Reaktionen tertiärer Alkoxy-Radikale sind aufgrund der eingeschränkten Verfügbarkeit der Radikalvorläufer bis dato auf intermolekulare Additionen an Norbornen beschränkt (Schema 2.4).<sup>[37]</sup> Da die Verwendung tertiärer *O*-Radikale in Radikalcyclisierungen neue Synthesewege zu einer Vielzahl von Naturstoffen eröffnen würde, ist die systematische Untersuchung solcher Radikale von besonderem Interesse (Schema 2.5).

**Schema 2.5.** Retrosynthese von Davanon über das Sauerstoff-Radikal-Verfahren.

## 2.3 Aufgabenstellung

Vor dem Hintergrund des dargelegten Forschungsstands widmet sich die vorliegende Arbeit folgenden Themenfeldern der Sauerstoffradikalchemie:

- Synthese anellierter und verbrückter *O*-Alkylthiohydroxamate und Untersuchung der Selektivität in 4-Penten-1-oxyl-Radikalcyclisierungen beim Aufbau bicyclischer und tricyclischer Tetrahydrofurane.
- Weiterentwicklung der Isoharnstoff-Methode zur Darstellung einer größeren strukturellen Vielfalt tertiärer *O*-Radikalvorläufer im präparativen Maßstab.
- Untersuchung der Reaktivität tertiärer *O*-Radikale in intra- und intermolekularen Additionsreaktionen sowie der  $\delta$ -H-Abstraktion.

## 3 Bi- und tricyclische Tetrahydrofurane aus substituierten 4-Penten-1-oxyl-Radikalen

### 3.1 Zusammenfassung

Bei 1,2- und 2,3-anellierten 4-Penten-1-oxyl-Radikalen steuert der näher zur  $\pi$ -Bindung lokalisierte Substituent, als primärer Induktor, den stereochemischen Verlauf der 5-*exo-trig*-Cyclisierung 2,4-*cis*- bzw. 2,3-*trans*-selektiv. Der Substituent mit größerer Distanz zur Doppelbindung fungiert als sekundärer Induktor. Seine relative Konfiguration zum primären Induktor erhöht die Diastereoselektivität im Falle einer *trans*-Konfiguration und senkt sie, wenn beide Substituenten *cis* zueinander angeordnet sind. 3,4-Anellierte sowie 2,5- und 3,5-verbrückte 4-Penten-1-oxyl-Radikale mit eingeschränkter konformeller Flexibilität der Sauerstoffatom-tragenden Seitenkette cyclisieren 2,3-*cis*- bzw. 2,4-*cis*-spezifisch. Der 2,3-*cis*-spezifische Ringschluss eines Verbenylethoxyl-Radikals liefert zwei  $\beta$ -bromierte, tricyclische Tetrahydrofurane. Theoretischen Berechnungen zufolge sind Torsionsspannungen dafür verantwortlich, dass die Aktivierungsbarriere der 2,3-*trans*-Cyclisierung 55 kJ/mol höher ist als die Barriere für den 2,3-*cis*-Ringschluss, weshalb 2,3-*trans*-Produkte des Verbenylethoxyl-Radikals experimentell nicht beobachtet werden

### 3.2 Wissenschaftlicher Hintergrund, Zielsetzung und Strategie

Eine Extrapolation von Richtlinien<sup>[1]</sup> zur Beschreibung von Selektivitäten beim Aufbau monocyclischer Verbindungen ist in den seltensten Fällen auf bicyclische Zielmoleküle übertragbar, da transannulare und andere Spannungseffekte in kaum vorhersagbarer Weise überlagern. Einflüsse cyclischer Substrukturen auf Stereoselektivitäten von 4-Penten-1-oxyl-Radikalcyclisierungen in der Synthese bicyclischer Tetrahydrofurane lassen sich jedoch durch systematische Permutation des Verbrückungsschemas (Typ **A–E**, Abb. 3.1) erfassen und zur Weiterentwicklung stereochemischer Richtlinien nutzen.<sup>[2,3]</sup>

• *exo-cyclische  $\pi$ -Bindung*

• *endo-cyclische  $\pi$ -Bindung*

**Abbildung 3.1.** Anellierte (Typ A–C) und verbrückte (Typ D–E) 4-Penten-1-oxyl-Radikale. Gestrichelte Linie: cyclischer Rest / Verbrückung.

Dem dargelegten Hintergrund folgend, hatte das Projekt zum Ziel,

- den dominierenden stereochemischen Einfluss des Substituenten zu identifizieren, der die Selektivitäten von 1 und 2 (Typ A), 2 und 3 (Typ B) sowie 3 und 4 (Typ C) cycloalkylverbrückter 4-Penten-1-oxyl-Radikale in 5-*exo*-Cyclisierungen steuert und
- die Systematik von Stereoselektivitäten in 5-*exo*-Cyclisierungen von 4-Penten-1-oxyl-Radikalen mit *endo*-cyclischen Doppelbindungen zu untersuchen (Typ D–E).

### 3.3 Ergebnisse und Diskussion

#### 3.3.1 Synthese und Eigenschaften anellierter und verbrückter O-Alkylthiohydroxamate

Die Synthese der Thiohydroxamsäure-O-ester **1a–1h** für die experimentell angestrebten Untersuchungen erfolgte durch selektive O-Alkylierung des 3-Hydroxy-4-methylthiazol-2(3*H*)-thion Tetraethylammonium-Salzes mit substituierten 4-Pentenyltosylaten (Salz-Methode, Schema 3.1). Sekundäre O-Alkylthiohydroxamate (*cis/trans*-**1a–1c**) reagieren unter Inversion der Konfiguration zu stereochemisch homogenen Produkten.<sup>[4]</sup>

**Schema 3.1.** Salz-Methode (oben) zur Herstellung der anellierten und verbrückten Thiohydroxamsäure-*O*-ester **1a–1h** (unten).

Die *O*-Radikalvorläufer wurden als farblose bis blassgelbe Öle (**1a–b**, *cis*-**1c**, **1f**) oder als farblose Feststoffe (*trans*-**1c**, **1d–e**, **1g**, **1h**) isoliert. Für 3-[(1-Methylcyclohex-1-en-4-yl)methoxy]-4-methylthiazol-2(3*H*)-thion (**1g**) zeigte die Kristallstrukturanalyse zwei Diastereomere entlang der stereogenen Achse [N3–O1] (Abb. 3.2). Beide nehmen eine Konformation ein, die aus dynamischen NMR-Studien von 3-Isopropoxy-4-methylthiazol-2(3*H*)-thion bekannt ist.<sup>[5]</sup> Um Abstoßungen durch die Thiocarbonyl- [C2,S2] und die Methyl-Gruppe [C6] auszuweichen, stehen Heterocyclus und Hexenyl-Rest dabei nahezu orthogonal zueinander [C2–N3–O1–C7 = 91.0(2)°].

**Abbildung 3.2.** Ellipsoid Graphik (50% Wahrscheinlichkeit) des Hauptdiastereomers von 3-[(1-Methylcyclohex-1-en-4-yl)-methoxy]-4-methylthiazol-2(3*H*)-thion (**1g**) im Kristall (150 K). Wasserstoffatome: farblose Kreise (willkürlicher Radius); Sauerstoff: rot, Stickstoff: blau, Schwefel: orange. C2–S2 = 1.666(1) Å, C2–N3 = 1.358(2) Å, N3–O1 = 1.386(2) Å.

Die *O*-Alkylthiohydroxamate **1a–1h** absorbieren UV/Vis-Licht im Bereich von 317–319 nm und zeigen charakteristische  $^{13}\text{C}$ -NMR-Verschiebungen für den Thiocarbonyl-Kohlenstoff (C2: 180 ppm), den Kohlenstoff in Position 5 des Thiazol-2(3*H*)-thion-Kerns (C5: 102 ppm) und die Ester-Kohlenstoffe (C7: 74.8–92.1 ppm), wobei *trans*-konfigurierte Ester **1a–1e** einen stärkeren Tieffeld-Shift für Sauerstoff-gebundene Kohlenstoffe (C7) zeigen als die *cis*-Stereoisomere.<sup>[6]</sup>

### 3.3.2 Typ A: 1,2-anellierte *O*-Alkylthiohydroxamate

Thermische und photochemische Reaktionen der 1,2-Cyclopentyl-anellierten Thiohydroxamsäure-*O*-ester **1a–1b** mit Bromtrichlormethan liefern nur geringe Mengen der  $\beta$ -bromierten Oxabicyclen **2a–2b** (Tabelle 3.1). Als Hauptprodukte entstehen die  $\delta$ -Bromaldehyde **3a–3b**. Die 1,2-Cyclohexyl-anellierten-Analoga *cis/trans*-**1c** cyclisieren selektiv zu den Tetrahydrofuranen *cis/trans*-**2c** und bilden nur bei thermischen Reaktionsbedingungen das  $\delta$ -Bromaldehyd **3c** als Nebenprodukt (Tabelle 3.2).

**Tabelle 3.1.** Produkte thermischer und photochemischer Umsetzungen der 1,2-Cyclopentyl-anellierten Thiohydroxamsäure-*O*-ester *cis/trans*-**1a** und *cis*-**1b** mit Bromtrichlormethan

Typ-**A**-anellierte 4-Penten-1-oxyl-Radikale (*cis/trans*-**1c**) cyclisieren 2,4-*cis*-selektiv und demonstrieren damit, dass der dominierende Stereoinduktor für Ringschlussreaktionen

der Substituent in Position 2 ist. Betrachtungen mit Hilfe eines erweiterten Twist-Modells zeigen, dass die 2,4-*cis*-Cyclisierungen aufgrund von Abstoßungen in den *trans*-Übergangszuständen bevorzugt wird (Abb. 3.2).

**Abbildung 3.2.** 5-*exo*-Übergangszustände cyclohexyl-anellierter Typ-A-Radikale (schwarze Kreise: räumlich nahe H-Atome; weiße Kreise ekliptisch angeordnete H-Atome).

1,2-Cyclopentyl-anellierte 4-Penten-1-oxyl-Radikale fragmentieren aufgrund der signifikanten Cyclopentylspannung<sup>[12]</sup> in hohem Maße (Tabelle 3.1). Mengen an Cyclisierungsprodukten steigen dabei für *cis*-konfigurierte Radikalvorläufer (*cis*-**1a**) sowie in Gegenwart terminaler Methylgruppen (*cis*-**1b**). Mit einem 60:40-Verhältnis zwischen Cyclisierung und Fragmentierung ist für 4-Penten-1-oxyl-Radikale mit dem gespannten Fünfring das beste Resultat erreicht (Tabelle 3.1, Eintrag 3).

Die relative Reaktivität zwischen Addition ( $k^{5-exo}$ ) und Fragmentierung ( $k^{Frag}$ ) der Radikale **1a–1c** ( $c_{1a-1c} = 0.167$  M, Schema 3.2) spiegelt sich in den Ausbeuteverhältnissen der Produkte **[2]**/**[3]** wider, da für beide Reaktionen kinetische Kontrolle sowie Bedingungen *pseudo*-erster Ordnung ( $c_{Br} = 1.67$  M) vorliegen.<sup>[7,8]</sup> Für die Fragmentierung basiert diese Näherung auf der höheren effektiven Geschwindigkeitskonstante des Bromeingangs ( $k_{eff}^{Br} = 4.3 \times 10^8$  s<sup>-1</sup>) der Radikale **IIIa–c** im Vergleich zur 5-*exo*-Cyclisierung des 4-Formylbutyl-Radikals ( $k^{5-exo} = 8.7 \times 10^5$  s<sup>-1</sup>, 80 °C).<sup>[9]</sup>  $k_{eff}^{Br}$  wurde aus der Bromtrichlormethan-Konzentration  $c_{Br}$  und der Geschwindigkeitskonstante des Bromatomeingangs  $k^{Br}$  des Hept-6-en-2-yl-Radikals ( $k^{Br} = 2.6 \times 10^8$  M<sup>-1</sup> s<sup>-1</sup>, 26 °C)<sup>[10]</sup> abgeschätzt. Das Verhältnis zwischen 4-Penten-1-oxyl-Radikalcyclisierung ( $k^{5-exo} = 5.2 \times 10^8$  s<sup>-1</sup>, 26 °C)<sup>[11]</sup> und Cyclopentoxyl-Radikalfragmentierung ( $k^{Frag} = 4.8 \times 10^8$  s<sup>-1</sup>, 80 °C)<sup>[9]</sup> erlaubt als Referenzsystem Rückschlüsse auf absolute Geschwindigkeitskonstanten für die Reaktion der Radikale **1a–1c**.

**Schema 3.2** Konkurrenzkinetische Betrachtung der Fragmentierung ( $k^{\text{Frag}}$ ) und 5-*exo*-Addition ( $k^{5\text{-exo}}$ ) der Typ-A-Radikale **Ia-c** für die mechanistische Interpretation der Reaktivität und Chemoselektivität.

### 3.3.3 Typ B: 2,3-anellierte O-Alkylthiohydroxamate

Die 2,3-Cyclohexyl-anellierte Thiohydroxamate *cis/trans*-**1d** reagieren in photochemischen und thermischen Umsetzungen mit Bromtrichlormethan zu diastereomeren Mischungen der anellierten-Tetrahydrofurane *cis/trans*-**2d**. Als Nebenprodukte entstehen die Tetrahydropyrane *cis/trans*-**4d** (Tabelle 3.3, Eintrag 1–4). Die Prenyl-abgeleiteten Typ-B-Derivate *cis/trans*-**1e** cyclisieren innerhalb der NMR- und GC/MS-Nachweisgrenze stereo- und regiospezifisch zum 5-*exo*-Bicyclus 6,7-*trans*-**2e**.

**Tabelle 3.3.** Produkte thermischer und photochemischer Cyclisierungen der 2,3-anellierten Thiohydroxamate *cis/trans*-**1d–1e** mit Bromtrichlormethan

Eintrag	<b>1</b> <sup>a</sup>	Bedingungen	R	<b>2</b> / % (6,7- <i>cis</i> : <i>trans</i> )	<b>4</b> / % (1,2- <i>cis</i> : <i>trans</i> )	<i>exo:endo</i>

<sup>a</sup> Stereodeskriptor für relative Konfiguration der Anellierung, <sup>b</sup> innerhalb der GC/MS- und NMR-Nachweisgrenze nur ein Isomer detektiert, <sup>c</sup> nicht beobachtet (NMR, GC/MS).

Der 2,3-*trans*-selektive Ringschluss 2,3-anellierter 4-Penten-1-oxyl-Radikale (Typ-B) verdeutlicht, dass die Stereochemie maßgeblich durch den Substituent bestimmt wird, der näher zur Doppelbindung steht (Position 3). Ursache der 2,3-*trans*-Selektivität ist, dem erweiterten Twist-Modell zufolge (Abb. 3.3), die sterische Hinderung zwischen den H-Atomen der  $\pi$ -Bindung und der Cyclohexyl-Einheit während des 2,3-*cis*-Ringschlusses. Für terminale Methyl-Gruppen nimmt die räumliche Abstoßung zu.

**Abbildung 3.3.** Übergangszustände der Typ-B-Vorläufer **1d/e** (schwarze Kreise: H-Atome, die an 1,3-diaxialen Abstoßungen beteiligt sind; weiße Kreise: ekliptisch angeordnete H-Atome).

### 3.3.4 Typ C: 3,4-anelliertes O-Alkylthiohydroxamat

Das 3,4-Cyclohexyl-anellierte Thiazol-2(3*H*)-thion **1f** cyclisiert in Gegenwart von Bromtrichlormethan, photochemisch wie thermisch, unter stereospezifischer Bildung des Oxabicyclus (±)-*cis*-**2f** (Tabelle 3.4). Darüber hinaus entsteht mit einem relativen Anteil von maximal 47% das 6-*endo*-Produkt 1-Bromo-3-oxabicyclo[4.4.0]decan (**4f**).

**Tabelle 3.4.** Produkte des Typ-C-Vorläufers **1f** der thermischen und photochemischen Umsetzungen mit Bromtrichlormethan

Eintrag	Bedingungen	<i>cis</i> - <b>2f</b> / %	<b>4f</b> / % (1,6- <i>cis:trans</i> )	<i>exo:endo</i>
1	$h\nu$ / 25 °C	24	21 (19:81)	53:47
2	AIBN / 80 °C	35	22 (32:68)	61:39

Der 5-*exo*-Ringschluss des 3,4-anellierten 4-Penten-1-oxyl-Radikals **1f** kann aufgrund der eingeschränkten Flexibilität der Seitenkette nur 2,3-*cis*-spezifisch erfolgen (Schema 3.3).

**Schema 3.3.** Stereo- und regiochemischer Verlauf der *exo*- bzw. *endo*-Addition des Typ-C-Radikalvorläufers **1f** in Gegenwart von Bromtrichlormethan.

### 3.3.5 Typ D: 2,5-verbrücktes O-Alkylthiohydroxamat

Intramolekulare Additionen des 2,5-verbrückten Thiohydroxamsäure-*O*-esters **1g** liefern für thermische und photochemische Reaktionen mit Bromtrichlormethan die Bicyclen *cis*/*trans*-**2g** (Tabelle 3.5).

**Tabelle 3.5.** Produkte der 5-*exo*-Additionen des Cyclohexenyl-substituierten Thiohydroxamsäure-*O*-esters **1g** in Gegenwart von Bromtrichlormethan

Eintrag	Bedingungen	<i>trans</i> - <b>2g</b> / %	<i>cis</i> - <b>2g</b> / %	1,2- <i>cis:trans</i>
1	$h\nu$ / 25 °C	46	18	28:72
2	AIBN / 80 °C	58	14	19:81

Der 2,4-*cis*-stereospezifische 5-*exo*-Ringschluss des Typ-D-anellierten 4-Penten-1-oxyl-Radikals **1g** ist das Resultat der eingeschränkten Flexibilität der Sauerstoffatom-tragenden Seitenkette (Schema 3.4).

**Schema 3.4.** 5-*exo-trig*-Cyclisierung des Radikals **1g**.

### 3.3.6 Typ E: 3,5-verbrücktes O-Alkylthiohydroxamat

Die photochemische Umsetzung des 3,5-verbrückten Verbenol-abgeleiteten Thiohydroxamats **1h** mit Bromtrichlormethan bildet als Hauptprodukt den bromierten Oxa-tricyclus **5** neben geringen Mengen des Isomer **6** (Schema 3.5).

**Schema 3.5.** Produkte der photochemischen Umsetzung des 3,5-verbrückten Verbenol-Radikalvorläufers **1h** in Gegenwart von Bromtrichlormethan.

Die erhaltenen Tricyclen **5** und **6** entstehen durch Folgereaktionen der 5-*exo-trig*-Cyclisierung (**1h**→**IIh**). Zum Abbau von Ringspannung lagert die Cyclobutyl-Einheit in **IIh** um, sodass die stabileren Radikale **V** und **VI** gebildet werden. Der anschließende Radikaleinfang mit Bromtrichlormethan liefert die Produkte **5** und **6** (Schema 3.6).

**Schema 3.6.** Reaktionskaskade aus Cyclisierung, Umlagerung und Bromatomeinfang des Radikals **1h** bei der Bildung der Tricyclen **5** und **6**.

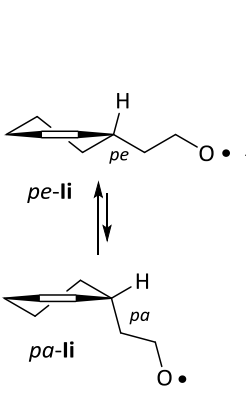

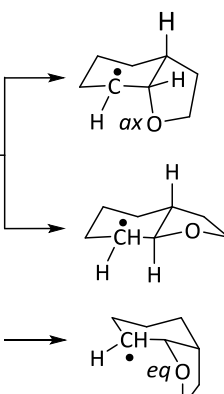

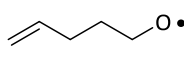

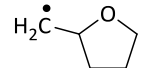

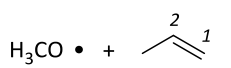

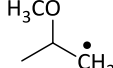

Typ-E-anellierte 4-Penten-1-oxyl-Radikale cyclisieren 2,3-*cis*-spezifisch, da die Flexibilität der Seitenkette eingeschränkt ist.

Um Barrieren abschätzen zu können, die mit dem *cis*- und *trans*-Ringschluss von **1h** verbunden sind, wurden in Kooperation mit Jens Hartung Energien für den *cis*- und *trans*-spezifischen Ringschluss des Modell-Radikals 1-(Cyclohexen-3-yl)-2-ethoxyl-Radikal **II**,

berechnet.<sup>[13,14]</sup> Die bekannten Energien der 5-*exo*-Reaktion des 4-Penten-1-oxyl-Radikals **Ij** wurden für den intramolekularen Vergleich herangezogen, während der energetisch ungünstige Angriff des Methoxyl-Radikals **Ik** an das interne Kohlenstoffatom (C2) von Propen aus struktureller Analogie zu den Radikalen **Ii** und **Ij** der Gegenüberstellung der intermolekularen Addition diente (Tabelle 3.6).<sup>[15,16]</sup>

Stark exotherme Reaktionsverläufe ( $\Delta_R E$ ) der betrachteten Radikale verdeutlichen eine kinetische Reaktionskontrolle mit frühen Übergangszuständen (Hammond-Postulat)<sup>[17]</sup> – Fakten, die sich bereits in früheren Studien mit der B3LYP/6-31+G\*\*<sup>-</sup>-Methode ausreichend beschreiben ließen.<sup>[18,19]</sup> Die Berechnungen liefern die Übergangsstrukturen *cis*-**IIIi** (*ax*), *cis*-**IIIi** (*eq*) und *trans*-**IIIi**, sowie die zugehörigen Reaktions- ( $\Delta_R E$ ) und Aktivierungsenergien ( $\Delta E^\ddagger$ ) (Tabelle 3.6).

**Tabelle 3.6.** Berechnete Übergangszustände und Energien (B3LYP/6-31+G\*\*<sup>-</sup>-Methode) der Alkoxy-Radikale *pe*-**Ii**, *pa*-**Ii**, **Ij** und **Ik**

Sauerstoff-Radikal	Kohlenstoff-Radikal	$\Delta_R E$ /kJ mol <sup>-1</sup>	$\Delta E^\ddagger$ /kJ mol <sup>-1</sup>	$\Delta E^\ddagger_i$ /kJ mol <sup>-1</sup>	$\Delta E^\ddagger_{TD}$ /kJ mol <sup>-1</sup>
					
<i>pe</i> - <b>Ii</b>	<i>cis</i> - <b>IIIi</b> ( <i>ax</i> )	-44.1	16.7	35.4	-18.6
	<i>trans</i> - <b>IIIi</b>	-34.5	73.1	89.5	-16.4
<i>pa</i> - <b>Ii</b>	<i>cis</i> - <b>IIIi</b> ( <i>eq</i> )	-46.8	17.4	37.1	-19.7
<hr/>					
 <b>Ij</b>	 <b>IIj</b>	-40.5	19.8	37.3	-17.5
 <b>Ik</b>	 <b>III</b>	-53.8	20.5	43.2	-22.7

Unter Verwendung der Marcus-Theorie<sup>[20–22]</sup> (Gleichungen 1 und 2) können die berechneten Werte für  $\Delta_R E$  und  $\Delta E^\ddagger$  Informationen über Energien der Bindungsbildung bzw. -lösung ( $\Delta E^\ddagger_{TD}$ ) und über sterische Effekte ( $\Delta E^\ddagger_i$ ) liefern. Die Berechnungen zeigen, dass der 2,3-*cis*-Ringschluss von **Ii** (**1h**) energetisch deutlich günstiger ist als die 2,3-*trans*-Cyclisierung.

Eine intrinsische Barriere ( $\Delta E_i^\ddagger$ ) von fast 90 kJ/mol ist dafür verantwortlich, dass 2,3-*trans* Produkte experimentell nicht entstehen (Tabelle 3.6).

$$\Delta E^\ddagger = \Delta E_i^\ddagger + \Delta E_{TD}^\ddagger \quad (\text{Gleichung 1})$$

$$\Delta E_i^\ddagger = \frac{\Delta E^\ddagger - \frac{\Delta_R E}{2} + \sqrt{(\Delta E^\ddagger)^2 - (\Delta_R E)(\Delta E^\ddagger)}}{2} \quad (\text{Gleichung 2})$$

### 3.4 Fazit und Ausblick

Anellierte und verbrückte 4-Penten-1-oxyl-Radikale cyclisieren in stereochemisch vorhersagbarer Weise. Für anellierte Substrate des Typs **A** und **B** dominiert der näher zur Doppelbindung befindliche Substituent (primärer Induktor) über die Stereochemie der 5-*exo*-Reaktion, sofern es sich um gleiche Reste handelt. Die relative Konfiguration beider Substituenten zueinander verbessert (*trans*) oder verschlechtert (*cis*) die Stereoselektivität. Verbindungen mit konformell eingeschränkter Seitenkette cyclisieren *cis*-spezifisch an *exo*- und *endo*-cyclische  $\pi$ -Bindungen (Typen **C–E**). Daraus lässt sich ableiten, dass 4-Penten-1-oxyl-Radikale mit drei gleichen Induktoren in den Positionen 1, 2 und 3 vermutlich der hier erkennbaren stereochemischen Prioritätsabstufung folgen, wonach der Einfluss der Induktoren mit zunehmendem Abstand zur Doppelbindung sinkt. Denkbar ist darüber hinaus, dass Substituenten größerer Sterik (z.B. *tert*-Butyl) in Positionen mit geringerem stereochemischen Einfluss (z.B. Position 2) Induktoren höherer Hierarchie (z.B. Methyl in Position 3) zu übersteuern vermögen und der Übersteuerungseffekt durch Substituenten unterschiedlicher Polarität beeinflusst werden kann. Diese Hypothesen sind Ziele zukünftiger Arbeiten und tragen dazu bei, die derzeitige Vielfalt Tetrahydrofuran-abgeleiteter Derivate in der Synthesechemie um weitere bi-, tri- oder sogar polycyclische Teilstrukturen zu bereichern.

## Annulated and bridged tetrahydrofurans from alkenoxyl radical cyclization†‡

Christine Schur,<sup>a</sup> Harald Kelm,<sup>a</sup> Thomas Gottwald,<sup>b</sup> Arne Ludwig,<sup>b</sup> Rainer Kneuer<sup>b</sup> and Jens Hartung<sup>\*a</sup>

4-Pentenoxy radicals sharing two or more carbon atoms with a cycloalkane cyclize in a predictable manner stereoselectively and regioselectively to afford in solutions of bromotrichloromethane cycloalkyl-fused or -bridged 2-bromomethyltetrahydrofurans in up to 95% yield. Stereoselectivity in alkenoxyl radical ring closures arises from cumulative steric effects. The substituent positioned the closest to the alkene carbon, which is being attacked by the oxygen radical, exerts the strongest stereodirecting effect. This principal inductor guides 5-*exo*-cyclization 2,3-*trans*- or 2,4-*cis*-selectively. The substituent located further from the attacked  $\pi$ -bond is the secondary inductor. A secondary inductor in the relative *trans*-configuration enhances stereodifferentiation by the primary inductor; a *cis*-configured secondary inductor decreases this effect. A secondary inductor is not able to overrule the guiding effect of a similar sized primary inductor. Intramolecular 4-pentenoxy radical additions to a cyclohexene-bound *exo*-methylene group or to endocyclic double bonds proceed *cis*-specifically, as exemplified by synthesis of a diastereomerically pure bromobicyclo[2.2.1]heptyl-annulated tetrahydrofuran from the verbenylethyloxy radical. According to theory, the experimental 2,3-*cis*-specificity in alkoxy radical cyclization to an endocyclic  $\pi$ -bond arises from strain associated with the 2,3-*trans*-ring closure.

## 1. Introduction

4-Pentenoxy radicals add intramolecularly to the inner alkene carbon with rate constants of  $10^8$  per second and above.<sup>1–6</sup> Alkyl or *ortho*-substituted aryl groups in position 1 exert a stereodirecting effect, leading to 2,5-*trans*-configured tetrahydrofurans as principal products. Carbon substituents at positions 2 and 3 direct 4-pentenoxy radical cyclization 2,4-*cis*- and 2,3-*trans*-selectively.<sup>7–9</sup> Stereodifferentiation by alkyl or aryl groups arises from steric effects, which gradually increases as the distance between a controlling substituent and the attacked  $\pi$ -bond shortens, for example from a 15/85-*cis/trans*-

ratio at room temperature to <2/98 by shifting a *tert*-butyl group from position 1 to position 3.<sup>8</sup> In synthesis, 5-*exo*-cyclized 4-pentenoxy radicals are preferentially trapped by a heteroatom atom donor,<sup>10,11</sup> for introducing halogen,<sup>12–14</sup> alkylsulfanyl,<sup>15</sup> or other synthetically useful functional groups.<sup>16</sup>

The model to explain stereodifferentiation by a carbon substituent in 4-pentenoxy radical cyclization predicts that the intramolecular addition proceeds *via* a distorted twist-conformer of tetrahydrofuran as the favored transition structure (twist-model),<sup>8,17</sup> differing from the cyclohexane-based Beckwith-Houk-model for carbon radical cyclization.<sup>18,19</sup> Application of the alkoxy radical approach to synthesis of more demanding targets, for example biologically active terpene-, acetogenin-, and fatty acid-derived cycloalkyl-fused tetrahydrofurans,<sup>20–22</sup> requires to extend the model in order to predict the selectivity for constructing bicyclic compounds.<sup>7,23</sup> Lessons from carbon radical chemistry have taught that stereodifferentiation in synthesis of bicyclic compounds is difficult to extrapolate by transferring results from monocycle to bicycle formation, since transannular and other strain effects may superimpose in an unpredictable manner.<sup>24,25</sup> To find out whether embedding two carbons of a 4-pentenoxy radical into a cycloaliphatic framework conserves or changes guidelines for stereoselective tetrahydrofuran synthesis, we examined in this study bromocyclization of *cis/trans*-cycloalkyl-bridged alkenoxyl

**Fig. 1** Classification of cycloalkyl-bridged 4-pentenoxyl radicals (type A–C) and alkenoxyl radicals having an endocyclic carbon–carbon double bond (type D–E; dotted red lines symbolize alkyl bridging).

radicals, having the carbon–carbon double bond located in a conformationally flexible side chain (types A and B), in the *exo*-position of cyclohexane (type C), or incorporated into an alicyclic core (types D and E, Fig. 1).

The most important finding from the study shows that cycloalkyl-bridged 4-pentenoxyl radicals cyclize in a predictable manner stereoselectively and regioselectively, to afford in solutions of bromotrichloromethane cycloalkyl-annulated or -bridged bromomethyltetrahydrofurans in up to 95% yield. The principal stereoinductor is the substituent attached the closest to the carbon–carbon double bond, which is being attacked by the radical oxygen. A principal inductor guides 5-*exo*-cyclization 2,3-*trans*- or 2,4-*cis*-selectively. The substituent bound further from the attacked  $\pi$ -bond is the secondary inductor. A *trans*-arranged secondary inductor enhances stereocontrol of the primary inductor, and a *cis*-configured secondary inductor decreases this effect. A secondary inductor of similar steric size, located further from the attacked  $\pi$ -bond is not able to overrule the directing effect of the principal inductor. Oxygen radicals attached *via* a methylene- or an ethylene-spacer to cyclohexene cyclize *cis*-specifically, as exemplified by synthesis of a diastereomerically pure bromobicyclo[2.2.1]-heptyl-annulated tetrahydrofuran from a type-E radical. The propensity of cyclohexenylethoxy radicals to cyclize 2,3-*cis*-specifically arises from strain associated with the 2,3-*trans*-ring closure, as derived by a Marcus analysis of density functional-calculated reaction energies and barriers.

## 2. Results and interpretation

### 2.1 Alkenoxyl radicals from 3-alkenoxy-4-methylthiazole-2(3H)-thiones

**2.1.1 Alkenoxyl radical generation, intramolecular addition, and chain reaction.** In extension to previous studies, we used derivatives of 3-alkenoxy-4-methylthiazole-2(3H)-thione (MTTOR) **1** as progenitors for generating oxygen radicals under non-oxidative and pH-neutral conditions.<sup>11,26,27</sup> MTTORs (e.g. **1**) are heterocyclic *O*-alkenyl thiohydroxamates,

**Scheme 1** Chain mechanism for synthesis of annulated bromomethyl-tetrahydrofuran **3** from 3-alkenoxy-4-methylthiazole-2(3H)-thione **1** and  $\text{BrCCl}_3$  (the red dotted line symbolizes an alkyl-bridge; cf. Fig. 1 and Scheme 2).

liberating oxygen radicals in an addition/fragmentation sequence involving a mediator radical. The intermediate formed by adding, for example, the trichloromethyl radical to the thione sulfur of MTTOR **1** dissociates into 2-(trichloromethylsulfanyl)-4-methylthiazole **2** and oxygen radical **I** (Scheme 1).<sup>14</sup> 4-Pentenoxyl radicals cyclize by intramolecularly adding with rate constants of  $10^8$ – $10^9$   $\text{s}^{-1}$  at room temperature to a terminal double bond, providing tetrahydrofuranylmethyl radicals, for example **II**, in a fingerprint 5-*exo*/6-*endo*-regioselectivity of 98:2.<sup>17</sup> Trapping of carbon radical **II** by bromotrichloromethane yields bromomethyltetrahydrofuran **3** as a target product, and the trichloromethyl radical for propagating the chain reaction.

**2.1.2 Preparation and properties of 3-alkenoxy-4-methylthiazole-2(3H)-thiones (MTTORs).** The standard approach to synthesis of *O*-alkenyl thiohydroxamate **1** is substitution of a leaving group from a carbon electrophile by the 4-methyl-2-thioxothiazole-2(3H)-3-oxido ion ( $\text{MTTO}^-$ ; Scheme 2).<sup>26</sup> In the present study we used *O*-alkenyl tosylates as carbon electrophiles, obtained in 69–96% yield from an alkenol,<sup>28–31</sup> *p*-toluenesulfonyl chloride, and 1,4-diazabicyclo[2.2.2]octane for buffering *in situ*-liberated hydrogen chloride ( $\text{ESI}^+$ ).<sup>32</sup> Some alkenol syntheses required modification of the original instruction, for example for preparing *cis*- and *trans*-isomers of 2-(2-methylprop-1-enyl)-cyclohexylmethanol (for **1e**)<sup>33,34</sup> and  $\beta$ -verbenylethanol (for **1h**;  $\text{ESI}^+$ ).<sup>35</sup> Treating *O*-pentenyl tosylates at room temperature in solutions of dimethyl formamide with the tetraethylammonium salt of  $\text{MTTO}^-$  furnished MTTORs **1a**, **1b**, and **1d–h** in yields between 65% and 82% (Scheme 2). In position 2 substituted cyclohexyl tosylates gave stereochemically pure target products *cis*-**1c** and *trans*-**1c**, although in comparatively low yields. We explain this observation by steric shielding of the electrophilic carbon in 2-substituted cyclohexyl tosylates toward the incoming nucleophile, the  $\text{MTTO}^-$ -anion, in a  $\text{S}_\text{N}2$ -reaction.<sup>36</sup>

3-Alkenoxyl-4-methylthiazole-2(3H)-thiones obtained as described above are oils (**1a–b**, *cis*-**1c**, **1f**) or crystalline solids (*trans*-**1c**, **1d–e**, **1g**, **1h**), stable for months when stored in vials at room temperature. Recrystallizing 3-(methylcyclohexenyl)-

**Scheme 2** Indexing, yields, and structure formulas of MTTORs **1a–h** prepared from *O*-alkenyl tosylates and 3-hydroxy-4-methylthiazole-2(3*H*)-thione tetraethylammonium salt (segments drawn in red refer to subunits represented by dotted lines in Fig. 1 and in Scheme 1).

methoxy-thiazoethione **1g** removed a regioisomer, which had been formed with 5/95-selectivity as a by-product from the [4 + 2]-cycloaddition between isoprene and methyl acrylate, in the first step of the synthesis for constructing the 1,4-disubstituted cyclohexenyl nucleus.<sup>37,38</sup>

3-Alkenoxy-4-methylthiazole-2(3*H*)-thiones **1a–h** show diagnostic carbon-13 chemical shifts for the thiocarbonyl carbon (180–181 ppm) and the thiohydroxamate-bound carbon (74.8–92.1 ppm). The compounds absorb in solutions of methanol UV-light, leading to absorption-maxima at  $\lambda = 316\text{--}319\text{ nm}$  ( $\lg \epsilon \sim 3.10\text{--}3.19\text{ m}^2\text{ mol}^{-1}$ ). Photoexciting the tail end of this absorption band with 350 nm light causes the nitrogen–oxygen bond in **1** to break homolytically, liberating oxygen radicals without an externally added initiator.<sup>39</sup>

In solution, 3-alkoxy-4-methylthiazole-2(3*H*)-thiones show the phenomenon of hindered rotation about the nitrogen–oxygen bond, becoming apparent in nuclear magnetic resonance spectra of, for example, 3-isopropoxy-4-methylthiazole-2(3*H*)-thione by signal coalescence at  $-60^\circ\text{C}$ , and a twofold set of resonances below this temperature.<sup>40</sup> The lowest in energy conformer has the ester carbon C7 offset by almost 90 degrees from the thiohydroxamate plane, to prevent close contacts with the thione sulfur and methyl group in position 4 of the heterocyclic core.<sup>41</sup> The structure of 3-alkenyloxythiazoethione **1g** in the solid state corresponds to the predicted minimum

**Fig. 2** Ellipsoid graphic of 3-[(1-methylcyclohex-1-en-4-yl)-methyl-oxy]-4-methylthiazole-2(3*H*)-thione (**1g**) in the solid state [major diastereomer at 150 K; the (*R,P*)-isomer was arbitrarily chosen from the racemate (*R,P*)/(*S,M*)-**1g** for presentation (50% probability level); hydrogen atoms are drawn as circles of an arbitrary radius; oxygen is depicted in red, nitrogen in blue, and sulfur in orange; for depiction of the minor diastereomer (*S,P*)/(*R,M*)-**1g**, see the ESI†].

conformation of thiazoethione-derived *O*-alkyl thiohydroxamates in solution and in the gas phase. The crystals available for determining the structure of compound **1g** were systematically disordered showing, according to the model used for solving and refining the structure, a 78/22-ratio of diastereomers at crystallographic independent sites.† The diastereomers differ with respect to the configuration at C8/C8a (ESI†) and the helicity at the nitrogen–oxygen bond, showing both the characteristic offset of thiohydroxamate bound carbon 7 from the heterocyclic plane [major diastereomer (ds): C2–N3–O1–C7 =  $91.0(2)^\circ$ ; minor ds: C2–N3a–O1a–C7a =  $59.8(6)^\circ$ ] and bond lengths which are diagnostic for primary *O*-alkyl thiohydroxamates [major ds (Fig. 2): C2–S2 =  $1.666(1)\text{ \AA}$ , C2–N3 =  $1.358(2)\text{ \AA}$ , N3–O1 =  $1.386(2)\text{ \AA}$ ; minor ds (ESI†): C2–N3a =  $1.366(6)\text{ \AA}$ , N3a–O1a =  $1.373(4)\text{ \AA}$ ].<sup>42</sup>

**2.1.3 Numbering of atom positions in *O*-alkenyl thiohydroxamates, alkenoxyl radicals, and cyclized products.** Oxygen and carbon differ in priority for systematically naming open chain and heterocyclic organic compounds according to the IUPAC convention. For the stereochemical discussion in this article we numbered the 4-pentenyl chain in *O*-radical progenitor **1** and alkenoxyl radical **I** as recommended by IUPAC for aliphatic compounds.<sup>43</sup> A transition structure (TS)-**I** for 5-*exo*-cyclization in the twist model is a derivative of tetrahydrofuran, and thus numbered, similar to cyclized carbon radical **II**, according to the Hantzsch–Widman notation for heterocyclic compounds.<sup>44,45</sup> For numbering positions in bicyclic bromocyclization product **3**, we used the von Baeyer convention (Fig. 3).<sup>46,47</sup>

## 2.2 Alkenoxyl radical addition to exocyclic double bonds

**2.2.1 1,2-Annulation – 2-allylcycloalkyl-1-oxyl radical reactions.** For elucidating principles of stereocontrol exerted by a cycloalkane fused in positions 1 and 2 to the 4-pentenoxyl radical we investigated the size effect of the cycloaliphatic ring,

† Crystallographic data (excluding structure factors) for the structure in this paper are deposited with the Cambridge Crystallographic Data Centre as supplementary publication [CCDC 1008593 (compound **1g**)].

**Fig. 3** Convention used in this article for numbering atoms in product classes associated with alkoxy radical reactions, exemplified for alkenoxythiazolethione *cis*-1c, derived 4-alkenoxyl radical *cis*-1c, the transition structure for the 5-exo-cyclization TS-*cis*-1c, 5-exo-cyclized carbon radical *cis*-1c, and bicyclic bromocyclization product *cis*-3c.

the relative configuration of substituents, and substitution at the terminal alkene carbon on reactivity and selectivity of type-A alkenoxyl radicals (Tables 1–4).

(i) *Methods of alkenoxyl radical generation and product analysis.* Photolyzing solutions of *O*-alkenyl thiohydroxamates **1a–c** in benzene containing 10 equivalents (1.67 M) of bromotrichloromethane, using Rayonet® chamber apparatus equipped with 350 nm illuminants, quantitatively consume the starting material within 30 minutes, as determined by thin layer chromatography. Reaction mixtures from photochemical experiments tended to turn turbid and yellow. A gas chromatogram (GC) recorded by the end of the reaction time provided information on the original product pattern and distribution.

## Paper

Column chromatography furnished samples of purified 2-(trichloromethylsulfanyl)-4-methyl-1,3-thiazole (2), 5-*exo*-bromocyclized products **3a–c**, and  $\beta$ -fragmented unsaturated 5-bromoaldehydes **4a–b**, for collecting analytical data (Tables 1–4, and Experimental). Solutions from thermally initiated reactions were in addition charged with 15 mole percent of azo- $\alpha,\alpha$ -bis(isobutyronitrile) (AIBN) as the initiator. Such mixtures remained clear but tended to turn yellow by the end of the reaction.

(ii) *Product pattern and kinetic interpretation.* Reactions between *O*-(2-allylcycloalkyl) thiohydroxamates *cis*-**1a–c** and bromotrichloromethane furnish bromomethyltetrahydrofurans *cis*-**3a–c**, with the yields gradually decreasing for thermally initiated reactions from 61% for *cis*-**3c** through 34% for *cis*-**3b** to 8% for *cis*-**3a** (Table 1, entries 2 and 4; Table 3, entry 2). The reactions gave bromoaldehydes **4a–c** as co-products in yields increasing from 12% for **4c**, through 35% for **4b** to 54% to **4a**. Photolyzing or heating *O*-(2-allylcyclopentyl) thiohydroxamate *trans*-**1a** in the presence of bromotrichloromethane provided bromooctanal **4a**, but no bromomethyltetrahydrofuran *trans*-**3a** as secured by independent analysis of an authentic sample of the compound (ESI†). The ratio of the bromocyclized product *trans*-**3c** and bromoaldehyde **4c** obtained from *O*-cyclohexylallyl ester *trans*-**1c** is similar to the ratio of *cis*-**3c** and **4c** obtained from the stereoisomer *cis*-**1c** (entry 2 in Tables 3 and 4). The pattern of products obtained from radical reactions conducted at 80 °C in summary is similar, except for bromoaldehyde **4c**, which did not form in the room temperature experiments. None of the reactions furnished 2-allylcycloalkanols or 2-allylcycloalkanones in verifiable amounts (GC-MS).

In kinetically controlled reactions, the quotient between bromomethyltetrahydrofuran **3** and bromoaldehyde **4** is equivalent to the relative rate constant for the addition ( $k^{\text{add}}$ ) versus  $\beta$ -fragmentation ( $k^{\beta}$ ) (Scheme 3). Kinetic control for oxygen radical addition to terminal double bonds is documented.<sup>8</sup> For the following reason we suggest that the sequence leading to bromoaldehyde **4** under conditions chosen in this study also is kinetically controlled. In 1.67 molar solution of bromotrichloromethane, the effective rate constant for bromine atom trapping by secondary alkyl radicals, such as **III**, is approximately  $4.3 \times 10^8 \text{ s}^{-1}$ , based on  $k^{\text{Br}}$  for the 6-hepten-2-yl radical ( $2.6 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ ; 26 °C)<sup>48</sup> as a reference. The rate constant  $k^{\text{add}}$  for the 4-formylbutyl radical 5-*exo*-cyclization ( $8.7 \times 10^5 \text{ s}^{-1}$ ; 80 °C),<sup>49</sup> serving as a reference for the reaction **III**  $\rightarrow$  **I**, is by almost three orders of magnitude slower than the effective rate of bromine atom transfer from bromotrichloromethane to the secondary carbon radical **III**.

For comparing rates of 5-*exo*-cyclization to rates of  $\beta$ -fragmentation for intermediates **Ia–c**, we standardized reactant concentrations and used a tenfold molar excess of bromotrichloromethane. Under such conditions, the ratio of bromide **3** to **4** corresponds to the quotient  $k^{\text{add}}/k^{\beta}$ , gradually increasing along the series of radicals *trans*-**1a** ( $k^{\text{rel}} = 0$ ), *cis*-**1a** (0.2), *cis*-**1b** (1.0) to *cis*/*trans*-**1c** ( $k^{\text{rel}} = 5$ –9). Dividing  $k^{\text{add}}$  for the 4-pentenoxyl radical cyclisation ( $5.2 \times 10^8 \text{ s}^{-1}$ ; 26 °C) by  $k^{\beta}$  for the cyclopentoxyl radical  $\beta$ -fragmentation ( $4.7 \times 10^8 \text{ s}^{-1}$ ; 80 °C) for

## Organic &amp; Biomolecular Chemistry

**Scheme 3** Competing reaction pathways for mechanistically interpreting the origin and yields of 5-*exo*-cyclization- versus  $\beta$ -fragmentation-products from 2-allylcycloalkyloxy radicals **Ia–c** ( $R = \text{H}, \text{CH}_3$ ; for details associated with rate constants  $k^{\beta}$ ,  $k^{\text{Br}}$ , and  $k^{\text{add}}$ , see the text).

calibrating the competition system with the aid of absolute rate constants leads to a similar order of magnitude for the  $k^{\text{add}}/k^{\beta}$  ratio.<sup>2,49</sup>

The propensity of cyclopentane-fused 4-pentenoxyl radicals to provide  $\beta$ -fragmented products, such as bromoaldehydes **4a–b**, arises from strain, being  $\sim 20 \text{ kJ mol}^{-1}$  higher for cyclopentane than for cyclohexane.<sup>50</sup> Substituting methyl for hydrogen at the terminal alkene carbon increases the fraction of the 5-*exo*-cyclized product from *cis*-**3a** to *cis*-**3b**, which we address to a rate enhancing polar effect of the methyl group in oxygen radical additions.<sup>51</sup>

(iii) *Stereochemical guidelines.* 1,2-Cycloalkyl-bridged 4-pentenoxyl radicals **Ia–c** cyclize 2,4-*cis*-selectively showing that the substituent in position 2 is the principal stereoinductor for 5-*exo*-cyclization of type-A radicals. A *trans*-arranged secondary inductor in position 1 enhances the directing effect of the principal inductor; a *cis*-configured secondary inductor decreases this effect.

(iv) *On the origin of 2,4-*cis*-selectivity in 5-*exo*-cyclization of type-A 4-pentenoxyl radicals.* To understand the origin of 2,4-*cis*-selectivity, we modelled transition structures (TS) of 2-allylcyclohexyl-1-oxyl radical 5-*exo*-cyclization **Ic**  $\rightarrow$  **IIc**, using assessed electronic structure methods.<sup>14,52</sup>

For stereochemical analysis, we considered transition structures for 2,4-*cis*-(TS<sup>1</sup>) and 2,4-*trans*-cyclization (TS<sup>2</sup>) of allylcyclohexyloxy radicals *cis*/*trans*-**Ic** (Fig. 4 and ESI†; see also section 2.4). Transition structure searches according to an established methodology<sup>17</sup> (ESI†) led to twist (T)-conformers of tetrahydrofuran (Fig. 4), similar to intermediates modelled for 5-*exo*-cyclization of monosubstituted 4-pentenoxyl radicals.<sup>8</sup> The radical oxygen in transition structures TS<sup>1,2</sup>-*cis*/*trans*-**Ic** lies for stereoelectronic reasons in a plane defined by inner alkene carbon (C5) and the allylic carbon (C4). Carbons 2 and 3 are offset into opposite directions from this plane, leading to <sup>2</sup>T<sub>3</sub>-(TS<sup>2</sup>-*cis*-**Ic**, TS<sup>1</sup>-*trans*-**Ic**, and TS<sup>2</sup>-*trans*-**Ic**) and <sup>2</sup>T<sub>3</sub>-conformers of tetrahydrofuran (TS<sup>1</sup>-*cis*-**Ic**). *cis*/*trans*-Diastereodifferentiation, in this model, occurs by rotating the vinyl substituent by 180 degrees about the bond between carbons 4 and 5. Positioning the vinyl group and carbon 3 on opposite sides of the twist plane prevents eclipsing of hydrogens at carbons 4 and 5, thus favoring transition structures TS<sup>1</sup>-*cis*-**Ic** and TS<sup>1</sup>-*trans*-**Ic**. Favored transition structures furthermore have the cyclohexyl-

**Fig. 4** Modelled transition structures for 2,4-*cis* (TS<sup>1</sup>) and 2,4-*trans* (TS<sup>2</sup>)-cyclization of alkenoxyl radicals *cis*-1c (top) and *trans*-1c (bottom). Black circles represent hydrogens experiencing close contacts ( $d_{\text{H,H}} = 2.423 \text{ \AA}$ ; B3LYP/6-31+G\*\*), open circles symbolize eclipsed hydrogens ( $\text{H}-\text{C}4-\text{C}3-\text{H} = 2.1^\circ$ ). <sup>a</sup>Stereodescriptor referring to the configuration at carbons 2 and 4 in cyclized radical 1lc (cf. Fig. 3). <sup>b</sup>Stereodescriptor referring to the configuration at carbons 2 and 3 in TS-1c.

substituent in position 3 bound equatorially to the distorted tetrahydrofuran nucleus (Fig. 4). Positioning the cyclohexyl-substituent at carbon 3 axially leads to transannular repulsion between the hydrogen attached to carbon 5 and one of the axial cyclohexane hydrogens (TS<sup>2</sup>-*cis*-1c). The lowest in energy transition structure modelled for the 2,4-*trans*-ring closure of *trans*-1c (TS<sup>2</sup>-*trans*-1c; Fig. 4, bottom right) shows an eclipsing of hydrogens at carbons 4 and 5.

**2.2.2 2,3-Annulation – 2-(vinylcyclohexyl)-methyloxyl radical reactions.** For elucidating principles controlling the stereoselectivity in cyclization of 2,3-cyclohexyl-bridged 4-pentenoxyl radicals (type B), we investigated bromocyclization of 2-vinyl- and 3-(2-dimethylvinylcyclohexylmethyloxy)-thiazolethiones *cis*/*trans*-1d-e (Tables 5 and 6).

(i) *Methods of alkenoxyl radical generation and product analysis.* Thermally induced reactions between *O*-(2-vinylcycloalkyl-1-methyloxy) thiohydroxamates *cis*-1d/e and bromotrichloro-

4	<i>trans</i>	AIBN/80 °C	98	1,6- <i>trans</i> : 94 <sup>a</sup> (>99 : 1)

<sup>a</sup> Single diastereomer, according to proton-NMR- and GC-MS-data.

methane furnish 81% of 7-bromomethyltetrahydrofuran *cis*-3d and 95% of bromoisopropyl derivative *cis*-3e (entry 2 in Tables 5 and 6). The former reaction provided in addition 5% of the diastereomerically pure 6-*endo*-cyclized product *cis*-5d, which was not obtained from dimethylvinyl-congener *cis*-1e (GC-MS).

Heating *O*-(2-vinylcycloalkyl-1-methyloxy) thiohydroxamate *trans*-1d in the presence of bromotrichloromethane furnishes an 80/20-mixture of 5-*exo*/6-*endo*-bromocyclized products *trans*-3d and *trans*-5d, whereas *O*-[2-(dimethylvinyl)-cyclohexyl-methyl] ester *trans*-1e affords bromopropyltetrahydrofuran *trans*-3e as a single diastereomer (Tables 5 and 6, entry 4). Photochemical reactions gave 13–20% lower yields of bromocyclization products 3 and 5 taken together, and 8–19% less thiazole 2, than thermally initiated reactions (entries 1 and 3 in Tables 5 and 6).

(ii) *Effect of methyl substitution at the terminal alkene carbon.* Substituting two hydrogens at the terminal alkene carbon by methyl improves the stereoselectivity and regioselectivity in cyclization of type-B 4-pentenoxyl radicals (Tables 5 and 6). Terminal methyl groups furthermore improve the regioselectivity of the intramolecular addition, occurring with 80/20-selectivity for *trans*-1d, 94/6 for *cis*-1d, and 5-*exo*-specifically for *cis*/*trans*-1e (GC-MS; Table 5, entries 2 and 4, and Table 6).

<sup>a</sup> Stereodescriptor referring to the configuration of bridgehead carbons in products 3d and 5d.

**Fig. 5** Transition structure models for explaining the origin of 2,3-*trans*-stereoselectivity in 5-*exo*-cyclization type-B pentenoxy radicals, exemplified by favored intermediates TS<sup>1</sup>-*cis/trans*-Id and disfavored intermediates TS<sup>2</sup>-*cis/trans*-Id. Hydrogen atoms drawn as black circles give rise to 1,3-diaxial repulsion, eclipsically arranged hydrogens are drawn as open circles. <sup>a</sup>Stereodescriptor referring to the configuration at carbons 2 and 3 in cyclized radical Id (cf. Fig. 3). <sup>b</sup>Stereodescriptor referring to the configuration at carbons 3 and 4 in TS-Id.

(iii) *Stereochemical guidelines.* 2,3-Cycloalkyl-bridged 4-pentenoxy radicals **Id–e** cyclize 2,3-*trans*-selectively, indicating that the principal stereoinductor in cyclization of type-B radicals is the substituent in position 3 of the radical. Fusing 4-pentenoxy radicals in relative *trans*-positions of cyclohexane enhances stereodifferentiation by the principal inductor.

(iv) *On the origin of 2,3-*trans*-selectivity in 5-*exo*-cyclization of type-B 4-pentenoxy radicals.* Models built as instructed in section 2.1 show that type-B cyclohexyl-bridged 4-pentenoxy radicals *cis/trans*-Id–e cyclize 2,3-*trans*-selectively, because steric constraints disfavor the 2,3-*cis*-mode of ring closure. In transition structures for 2,3-*cis*-cyclization, van der Waals repulsion between the (*E*)-positioned alkene substituent and the axially arranged hydrogens raises conformational free energy. The second aspect raising conformational free energy thus disfavoring a transition structure is eclipsing of hydrogens bound to carbons 4 and 5 (for TS<sup>2</sup>-*trans*-Id and TS<sup>2</sup>-*cis*-Id; Fig. 5). Extending the size of the (*E*)-substituent from hydrogen to methyl raises transannular repulsion, explaining the stereo-directing effect of a terminal substituent in cyclization of *cis/trans*-Id.

**2.2.3 3,4-Annulation – 2-(2-methylenecyclohexyl)-1-ethyloxy radical reactions.** To explore the selectivity in intramolecular addition of a 3,4-cyclohexyl-bridged 4-pentenoxy radical (type C), we investigated photochemical and thermal reactions between 3-[2-(2-methylenecyclohexyl)-ethyloxy]-thiazolethione **1f** and bromotrichloromethane (Table 7).

(i) *Methods of alkoxy radical generation and product analysis.* 3-[2-(2-methylenecyclohexyl)-ethyloxy]-thiazolethione **1f** furnishes the 5-*exo*-bromocyclized product *cis*-**3f** as a single dia-

**Table 7** Products formed from 3-[2-(2-methylenecyclohexyl)-ethyloxy]-thiazolethione **1f** and BrCCl<sub>3</sub>

Entry	Conditions	2/%	<i>cis</i> - <b>3f</b> /%	<b>5f</b> /% ( <i>cis</i> : <i>trans</i> )

stereomer, bridgehead brominated oxadecalin **5f**, and 2-(trichloromethylsulfanyl)-thiazole **2**, when heated in the presence of bromotrichloromethane at 80 °C (Table 7, entry 2). The photochemical reaction provides a similar product pattern, although lower yields of compounds **2** and *cis*-**3f**. The fraction of bromotetrahydropyran **5f** remained almost unchanged (Table 7, entry 1).

The 5-*exo*/6-*endo*-selectivity of radical **If** (53 : 47) at room temperature falls below the value reported for the 4-methyl-4-pentenoxy radical (69 : 31) and is higher than the regioselectivity determined for the 4-*tert*-butyl-4-pentenoxy radical (46 : 54).<sup>17</sup> Regioselectivity in 4-pentenoxy radical cyclization originates from a balance between FMO attractions, torsional strain, and steric shielding. A carbon substituent in position 4 lowers the barrier for 6-*endo*-addition based on favorable frontier molecular orbital (FMO) interactions for the C,O-addition to the terminal carbon. Steric blocking of the incoming oxygen radical gradually lowers the rate of 5-*exo*-addition as the size of the carbon substituent in position 4 increases. The fraction tetrahydropyranyl radical **IVf** obtained from 6-*endo*-cyclization of **If** is in line with the general mechanistic interpretation.<sup>17</sup> Homolytic bromination of tetrahydropyranyl radical **IVf** occurs for steric reasons preferentially from the axial side (Scheme 4), similar to bromination of structurally related cyclohexyl radicals.<sup>53</sup>

(ii) *Stereochemical guideline.* Methylenecyclohexylethoxy radical **If** cyclizes 2,3-*cis*-specifically (Scheme 4).

**Scheme 4** Stereoselectivity in cyclization of the 1-methylenecyclohexyl-2-ethyloxy radical **If** (type C).

### 2.3 Cyclization onto endocyclic double bonds

For investigating the stereoselectivity in intramolecular addition to endocyclic double bonds we examined bromocyclization of 3-[2-(2-methylenecyclohexyl)-ethoxy]-thiazolethione **1g** (type D; section 3.1) and verbenylethanol-derived thiohydroxamate **1h** (type E; section 3.2).

**2.3.1 The (cyclohexen-4-yl)-methyloxy radical cyclization.** (i) *Methods of alkoxy radical generation and product analysis.* Photochemical and thermal reactions between 3-[(1-methylcyclohex-1-en-4-yl)-methoxy]-thiazolethione **1g** and bromotrichloromethane furnish the 5-*exo*-bromocyclized product **3g** and substituted thiazole **2** (Table 8, entries 1 and 2).

Bicyclic tetrahydrofuran **3g** forms at 80 °C as a 19/81-mixture of 1,2-*cis/trans*-stereoisomers. Resonances of protons in β- and γ-positions to the carbon–bromine bond experience a shift dispersion by ~0.5 ppm upon changing orientation of the bromosubstituent from anticlinal or antiperiplanar to synclinal (Table 8). We address this phenomenon to magnetic anisotropy induced by the carbon–bromine bond, possibly in combination with three nonbonding electron pairs at bromine.<sup>54</sup>

(ii) *Stereochemical guideline.* Cyclohexenylmethyloxy radical **1g** cyclizes 2,4-*cis*-specifically (Scheme 5).

**2.3.2 The verbenylethoxy radical cyclization.** (i) *Products from photochemical activation.* Verbenylethanol-derived thiohydroxamate **1h** furnishes tricyclic bromides **6** and **7** in a total yield of 61%, besides 79% of 2-(trichloromethylsulfanyl)-4-methylthiazole **2**, when photolyzed in the presence of bromotrichloromethane (Scheme 6).

(ii) *Stereochemical guideline.* Cyclohexenylethoxy radical **1h** cyclizes *cis*-specifically (Scheme 7).

**Scheme 5** 2,4-*cis*-cyclization of alkenoxy radical **1g** (type D; from **1g**).

(iii) *Verbenylethoxy radical chemistry.* In extension to the chemistry summarized in this article, we propose that tricyclic products **6** and **7** arise from a sequence composed of intramolecular addition **1h** → *cis*-**IIh**, ring-opening of cyclobutylmethyl radical *cis*-**IIh**, and bromine atom trapping by rearranged radicals **V** and **VI** (Scheme 7). 1,2-Shifting of the methylene bridge releases cyclobutyl strain in radical *cis*-**IIh**, leading to the secondary carbon radical **V**. For steric reasons, we expect trapping of the bicyclic radical **V** by bromotrichloromethane to occur from the concave face due to shielding of the convex side with the vicinal *exo*-oriented methyl group. The minor product **7**, according to the proposed model, results from 1,2-shifting of the dimethylmethylene bridge *cis*-**IIh** → **VI** and subsequent homolytic bromination.

### 2.4 Strain effects in alkoxy radical additions

For estimating differences in energy barriers associated with 2,3-*cis*- and 2,3-*trans*-cyclization of type-E alkenoxy radicals, we modelled energetics associated with 5-*exo*-cyclization using electronic structure methods.<sup>55,56</sup> The 2-(cyclohexen-3-yl)-ethoxy radical **II**, in this approach, served as a truncated model for the verbenyl-4-ethoxy radical **1h**, while the 4-pentenoxyl radical 5-*exo*-cyclization **Ij** → **IIj** and the methoxy radical addition to the inner carbon of propene served as references (Schemes 8 and 9).

(i) *Density functional theory.* For computing ground state energies of radicals and energies of transition structures, we used Becke's three parameter Lee–Young–Parr-hybrid functional (B3LYP)<sup>57,58</sup> and Becke's half and half Lee–Young–Parr hybrid functional (BHandHLYP)<sup>59</sup> in combination with 6-31+G\*\* and 6-311G\*\* basis sets.<sup>56</sup> All selected density functional/basis set combinations reproduce experimental stereo- and regioselectivity for oxygen radical addition to carbon–carbon double bonds with a precision coming close to the accuracy for determining experimental selectivity.<sup>8,14,17,52,60</sup>

(ii) *Theoretical approach.* For calculating equilibrium structures of conformational flexible molecules and transition structures associated with radical addition to carbon–carbon double bonds we used an established strategy.<sup>8,14</sup> According to theory, the 2-(cyclohexen-3-yl)-ethoxy radical **II** favors

**Scheme 6** Formation of bicyclic products from 3-(verbenylethoxy)-thiazole-2(3H)-thione **1h**.

**Scheme 7** Proposed pathways for product formation from verbenylethoxy radical **1h** (type E; from **1h**).

pseudo-equatorial (pe) positioning of the ethyloxy radical side to pseudo-axial (pa), as expressed by a modelled 90/10-mixture of pe/pa-conformers of **II** at 298 K (B3LYP/6-31+G\*\*); ESI $^\ddagger$ ). Both conformers served as starting points for modeling 5-*exo*-cyclizations.

Equilibrium structures of propene, alkoxy radicals **II-k**, cyclized radicals **III-j**, and the addition product **VIII** lack in negative eigenvalues of second derivatives of energy-minimized wavefunctions. Transition structures TS-I and TS-VII show one imaginary frequency  $i$ , describing the trajectory of oxygen radical addition to the inner alkene carbon (Table 9).<sup>61</sup>

Attempts to localize a transition structure for the *trans*-5-*exo*-cyclization of conformer pa-**II** led to TS<sup>1</sup>-*trans*-**II**, already available from conformer pe-**II**.

(iii) *Quality of the models.* Computed wavefunctions characterizing equilibrium structures show expectation values for the spin operator  $\langle S^2 \rangle$  close to 0.75 for oxygen and carbon radicals (ESI $^\ddagger$ ), as expected for doublet states. Wavefunctions describing transition structures show  $\langle S^2 \rangle$ -values of  $\sim 0.77$  for B3LYP-calculated intermediates and 0.82–0.84 for BHandHLYP-calculated transition structures (ESI $^\ddagger$ ). The effect of spin contamination in BHandHLYP-calculated transition structures was discussed previously, but is not considered relevant for attaining reasonable precision in determining computed relative energies.<sup>52</sup>

(iv) *Methoxyl radical addition to propene.* Theory predicts a lower barrier for methoxyl radical addition to the terminal carbon than for addition to the inner carbon of propene ( $\Delta G^{298} = -5.0$  to  $-8.5$  kJ mol $^{-1}$ ; ESI $^\ddagger$ ). The decision to compare structure and energetics from the disfavored mode of addition to data obtained for monocycle and bicycle formation was guided by structural similarity between TS-**II-j** and TS-VII on one side, and derived addition products **III-j**, **VIII** on the other (Table 9, Schemes 8 and 9).

(v) *Thermochemistry.* Cyclization of the 2-(cyclohexen-3-yl)-ethyloxy radical **II**  $\rightarrow$  **III**, according to zero-point energy corrected reaction energies (B3LYP/6-31+G\*\*), is for all considered

<sup>a</sup> B3LYP/6-31+G\*\*-calculated values; numbers in parentheses arise from BHandHLYP/6-31+G\*\*-calculations and values in brackets from BHandHLYP/6-311G\*\*-calculations. <sup>b</sup>  $i$  = imaginary mode of vibration. <sup>c</sup> O-C2 for TS<sup>2</sup>-VII. <sup>d</sup> O-C2-C1 for TS<sup>2</sup>-VII. <sup>e</sup> C-C2-H2-C1 for TS<sup>2</sup>-VII. <sup>f</sup> For the transition structure TS<sup>1</sup>-VII, refer to the ESI.

pathways strongly exothermic ( $\Delta_R E = -35$  to  $-47$  kJ mol<sup>-1</sup>), pointing to a notable barrier for the reverse reaction, the  $\beta$ -fragmentation. Computed energetics for the addition **Ii**  $\rightarrow$  **III** are similar to the values calculated for the 4-pentenoxyl radical ring closure **Ij**  $\rightarrow$  **IIj** ( $\Delta_R E = -41$  kJ mol<sup>-1</sup>), and are less exothermic than the methoxyl radical addition to the inner carbon of propene ( $\Delta_R E = -53$  mol<sup>-1</sup>). BHandHLYP-calculations provide similar trends for reaction energies, except for a stronger driving force for the intermolecular addition (Table 10).

(vi) *Transition structures*. The distance  $d$  between the radical oxygen and the attacked carbon, as predicted by B3LYP theory for transition structures of cyclohexenylethoxy radical cyclization (2.04–2.08 Å), 4-pentenoxyl radical cyclization (2.05 Å) and methoxyl radical addition to propene (2.06 Å), is marginally wider than those obtained from BHandHLYP-calculations (1.98–2.02 Å; Table 9). Values for the angle  $\alpha$  describing oxygen radical attack to the inner alkene carbon are grouped for all calculated transition structures in the range between 98 and

104 degrees, being more acute than the angle calculated for the highest in the energy transition structure TS-*trans*-II ( $^3\text{T}_4$ ) (121–122 degrees; Table 9). Absolute values of improper torsion angles  $\omega$  for transition structures TS-II, TS-Ij, and TS-VII, according to B3LYP- and BHandHLYP-theory, are close to 160 degrees, indicating the hybridization change at the attacked carbon from sp<sup>2</sup> ( $\omega = 180^\circ$  for propene) toward sp<sup>3</sup> (122° for propane).

Superimposing atomic coordinates of 4-pentenoxyl radical cores illustrates that density functional-calculated favored transition structures for the cyclohexenylethoxy radical cyclization and the 4-pentenoxyl radical ring closure are nearly identical (Fig. 6). A  $^3\text{T}_4$ -conformation, as predicted by theory for TS-*cis*-II ( $^3\text{T}_4$ ), is separated by only 36 degrees from a  $^2\text{T}_3$ -conformer in TS-Ij ( $^2\text{T}_3$ ) on the pseudorotatory cycle of tetrahydrofuran.<sup>62</sup>

(vii) *Energy barriers*. The barrier for 2,3-*cis*-cyclization of cyclohexenylethoxy radical **Ii** ( $\Delta E^\ddagger = 17$  kJ mol<sup>-1</sup>) is similar to the barrier predicted by B3LYP-theory for the 4-pentenoxyl radical 5-*exo*-cyclization (20 kJ mol<sup>-1</sup>) and the methoxyl radical addition to propene (21 kJ mol<sup>-1</sup>). BHandHLYP-computed barriers for 2,3-*cis*-cyclization of **Ii** and 5-*exo*-cyclization of **Ij** are higher, but generally show the same trends (Table 10).

The computed relative Gibbs free energy of activation for the 2,3-*trans*-mode of cyclization is 55 kJ mol<sup>-1</sup> above the value for the lowest in the energy pathway of 2,3-*cis*-ring closure (B3LYP; 58 kJ mol<sup>-1</sup> for BHandHLYP calculations using either the 6-31+G\*\* or the 6-311G\*\* basis set; ESI†). A Gibbs free activation energy difference of 55 kJ mol<sup>-1</sup> translates for a kinetically controlled reaction and a temperature of 298.15 K into a relative rate constant of  $4 \times 10^9$  in favor of the 2,3-*cis*-cyclization. Detecting a 2,3-*trans*-bromocyclized product with such a precision was beyond the capability of analytic instruments used in the study.

(viii) *Marcus analysis*. For analyzing strain and electronic effects on barriers of 5-*exo*-alkenoxyl radical cyclization, we split zero-point vibrational energy-corrected electronic barriers ( $\Delta E^\ddagger$ ) into an intrinsic ( $\Delta E^\ddagger_i$ ) and a thermodynamic term ( $\Delta E^\ddagger_{\text{TD}}$ ), using Marcus theory (Fig. 7, Table 10, eqn (1)–(3)).<sup>63–65</sup> The intrinsic part describes contributions of strain and steric repulsion in a thermoneutral degenerated reaction to the barrier  $\Delta E^\ddagger_i$  in a transition structure located half way on the reaction coordinate ( $x^\ddagger = 0.5$ ) between reactant(s) ( $x = 0$ ) and product(s) ( $x = 1$ ; Fig. 7). The thermodynamic part of the barrier  $\Delta E^\ddagger_{\text{TD}}$  describes energy changes arising from incipient bond forming and bond breaking in a transition structure.

$$\Delta E^\ddagger_i = \frac{\Delta E^\ddagger - \frac{\Delta_R E}{2} + \sqrt{(\Delta E^\ddagger)^2 - (\Delta_R E)(\Delta E^\ddagger)}}{2} \quad (1)$$

$$x^\ddagger = \frac{1}{2} \left( 1 + \frac{\Delta_R E}{4\Delta E^\ddagger} \right) \quad (2)$$

$$\Delta E^\ddagger = \Delta E^\ddagger_i + \Delta E^\ddagger_{\text{TD}} \quad (3)$$

(ix) *Localizing transition structures – the  $x^\ddagger$ -value*. According to Marcus theory, reaction energies and barriers obtained from

**Table 10** Zero-point vibrational energy-corrected activation energies ( $\Delta E^\ddagger$ ), reaction energies ( $\Delta_R E$ ), intrinsic energy barriers ( $\Delta E_i^\ddagger$ ), thermodynamic contribution  $\Delta E_{TD}^\ddagger$  to  $\Delta E^\ddagger$ , free energy differences [ $\Delta G^{298} = G^{298}(\text{I}) - G^{298}(\text{II})$  or  $\Delta G^{298} = [G^{298}(\text{Ik}) + G^{298}(\text{propene})] - G^{298}(\text{VIII})$ ] and approximated transition location  $x^\ddagger$  for alkoxy radical additions (Schemes 8 and 9, eqn (1)–(3))

**Fig. 6** Match plot of B3LYP/6-31+G\*\*-computed transition structures TS-cis-Ii ( ${}^3T_4$ ) (blue) and TS-Ij ( ${}^2T_3$ ) (yellow).

**Fig. 7** Potential energy curves  $E(x)$  for reaction associated with an energy change  $\Delta_R E$  across a barrier  $\Delta E^\ddagger$ , having an intrinsic barrier  $\Delta E_i^\ddagger$ , according to Marcus-theory, and harmonic potentials of the identical curvature for the initial ( $x = 0$ ) and final state ( $x = 1$ ).

B3LYP-calculations translate into a  $x^\ddagger$ -value of 0.2 for positioning transition structures on the respective reaction coordinates for C,O-addition (eqn (2)). Transition structures predicted from BHandHLYP-calculated energies are positioned later on the same reaction coordinate ( $x^\ddagger = 0.3$ –0.5), due to higher barriers  $\Delta E^\ddagger$ . Considering the magnitude of the experimental rate constant  $k^{\text{add}} = 5 \times 10^8 \text{ s}^{-1}$  for the 4-pentenoxyl 5-*exo*-cyclization **Ij**  $\rightarrow$  **IIj**<sup>2</sup> and computed significant reaction energies, we expect transition structures of alkoxy radical additions in extension to the Hammond-postulate<sup>66</sup> to be localized early on a reaction coordinate, rather than midway between reactant **I** and product **II**.

(x) *The role of the thermodynamic barrier.* In transition structures associated with alkoxy radical addition to alkenes, incipient carbon–oxygen bond formation and carbon–carbon  $\pi$ -bond breaking in summary is exothermic, lowering the intrinsic barrier by a thermodynamic contribution of  $-19$  to  $-20 \text{ kJ mol}^{-1}$ . This thermodynamic barrier  $\Delta E_{TD}^\ddagger$  is surprisingly similar for 2,3-*cis*- and 2,3-*trans*-ring cyclization of cyclohexenylethyloxy radical **Ii** ( $-16$  to  $-20 \text{ kJ mol}^{-1}$ ), the

4-pentenoxyl radical 5-*exo*-cyclization **Ij**  $\rightarrow$  **IIj** ( $-18 \text{ kJ mol}^{-1}$ ; B3LYP/6-31+G\*\*), and the barrier for methoxy radical addition to the inner carbon of propene ( $-23 \text{ kJ mol}^{-1}$ ). BHandHLYP-computed energies lead to more negative thermodynamic barriers, but show otherwise similar trends. From the data we concluded that the thermodynamic barrier is not the key parameter for explaining the experimental 2,3-*cis*-specificity of verbenylethyloxy radical cyclization.

(xi) *The role of the intrinsic barrier.* Intrinsic barriers modelled for 2,3-*cis*-cyclization of cyclohexenylethyloxy radical **Ii** ( $\Delta E_i^\ddagger = 35$ – $37 \text{ kJ mol}^{-1}$ , B3LYP; for BHandHLYP-calculated values, refer to Table 10) and 5-*exo*-cyclization of 4-pentenoxyl radical **Ij** ( $37 \text{ kJ mol}^{-1}$ ) are marginally smaller than the intrinsic barrier for methoxy radical addition to the inner carbon of propene ( $43 \text{ kJ mol}^{-1}$ ). An intrinsic barrier of  $90 \text{ kJ mol}^{-1}$  predicted for 2,3-*trans*-cyclization of the cyclohexenylethyloxy radical **Ii** exceeds the value for the barriers of all other investigated oxygen radical additions in the study by far. From this information we concluded that the experimentally observed 2,3-*cis*-stereospecificity of the verbenylethyloxy radical cycliza-

tion originates from a large intrinsic barrier associated with the 2,3-*trans*-ring closure.

### 3. Concluding remarks

Cycloalkyl-fused and -bridged 4-pentenoxyl radicals provide bicyclic and tricyclic tetrahydrofurans by 5-*exo*-cyclizations. The selectivity determining step is the intramolecular oxygen radical addition to the carbon–carbon double bond, occurring in most instances with notable stereochemical preference. From the observed stereoselectivities we concluded that a system exists, which can be summed up by two new directives for predicting the stereochemical outcome of similar cyclizations not exemplified in this article. The new guidelines supplement the set of existing directives, developed for predicting the major products in synthesis of monocyclic disubstituted tetrahydrofurans by the oxygen radical method.<sup>7,14,67</sup>

The first of the new guidelines ranks the hierarchy of two similarly sized stereoinductors by the distance between the alkyl group and the alkene carbon which is being approached by the oxygen radical. This guideline states that the substituent positioned the closest to the attacked alkene carbon is the principal (primary) inductor, guiding 5-*exo*-cyclization 2,3-*trans*- and 2,4-*cis*-selectively. The substituent bound further from the attacked  $\pi$ -bond is the secondary inductor, enhancing stereodifferentiation exerted by the principal inductor in the case of the *trans*-configuration, and decreasing this effect in the case of the *cis*-configuration. A secondary inductor is not able to overrule the guiding effect of a similarly sized primary inductor. The first guideline applies to 5-*exo*-cyclization of type-A and type-B 4-pentenoxyl radicals (Fig. 1).

The second new directive states that 4-pentenoxyl radical 5-*exo*-cyclization to a cyclohexene-bound *exo*-methylene group or an endocyclic double bond occurs *cis*-specifically. The second guideline refers to intramolecular addition of type-C–E radicals (Fig. 1).

From the hierarchy of similar-sized inductors we expect a substituent located in position 3 to also control the stereoselectivity in 5-*exo*-cyclization of 4-pentenoxyl radicals having similar sized substituents attached to carbons 1, 2, and 3. According to the first new guideline, a group in position 2 will be secondary and a group in position 1 the least effective, the tertiary inductor. From today's point of view we expect the stereoisomer of a 1,2,3-substituted 4-pentenoxyl radical corresponding to an all-*trans*-configured type-A and type-B radical to cyclize with notable 2,3-*trans*-, 2,4-*cis*-, and 2,5-*trans*-selectivity, possibly providing a single diastereomer. In the same model, a sterically more demanding substituent in position 2, for example *tert*-butyl, should be able to overrule the effect of a smaller group in position 3, such as methyl. Stereochemical questions of this kind attracted our attention and are being pursued at the moment in our laboratory, with the aim to provide new solutions to synthesis of functionalized ethers from oxygen radical addition to alkenes.

## 4. Experimental

### 4.1. General

For general laboratory practice and instrumentation see ref. 42 and the ESI.<sup>†</sup>

### 4.2. General methods

**4.2.1 3-Hydroxy-4-methylthiazole-2(3*H*)-thione tetraethylammonium salt (MTO<sup>−</sup>NEt<sub>4</sub><sup>+</sup>).** A solution of 3-hydroxy-4-methylthiazole-2(3*H*)-thione (MTOH; 1.3 mmol) in methanol (2 mL) was treated at 20 °C with a 1.5 M solution of tetraethylammonium hydroxide in methanol (0.87 mL, 1.3 mmol) and stirred for 1 hour. The solvent was removed under reduced pressure and the residue was freeze-dried for 12–14 hours.

**4.2.2 Synthesis of *O*-alkenylthiohydroxamates.** A suspension of 3-hydroxy-4-methylthiazole-2(3*H*)-thione tetraethylammonium salt (1.3 mmol) in anhydrous dimethyl formamide (1 mL) was treated at 20 °C with a solution of an alkenyl *p*-toluenesulfonate (1 mmol) in anhydrous dimethyl formamide (1 mL) for the time span specified in section 3. The resulting solution was stirred at 20 °C or 40–50 °C (for specific information, see synthetic procedures in section 4.3) diluted with dichloromethane (10 mL) and washed with an aqueous 2 M solution of sodium hydroxide (10 mL) and water (3 × 10 mL). The organic layer was separated, dried (MgSO<sub>4</sub>), and concentrated under reduced pressure to leave a residue, which was purified by chromatography (SiO<sub>2</sub>) or crystallized (solvent specification in section 4.3).

### 4.3 3-Alkenyloxy-4-methylthiazole-2(3*H*)-thiones

**4.3.1 3-[*cis*-2-(Prop-2-en-1-yl)-cyclopent-1-yloxy]-4-methylthiazole-2(3*H*)-thione *cis*-(1a).** From *trans*-2-(prop-2-en-1-yl)-cyclopent-1-yl 4-toluenesulfonate (4.22 g, 15.1 mmol); reaction time: 72 hours at 20 °C, the eluent used for chromatography: dichloromethane–pentane = 2 : 1 (v/v), *R*<sub>f</sub> = 0.51. Yield: 2.67 g (10.5 mmol, 70%), colorless oil.<sup>36</sup> <sup>1</sup>H-NMR (CDCl<sub>3</sub>, 600 MHz)  $\delta$  1.60–1.75 (m, 3 H), 1.80–1.84 (m, 1 H), 1.87–1.93 (m, 2 H), 2.03–2.06 (m, 1 H), 2.22 (d, *J* = 1.2 Hz, 3 H), 2.22–2.27 (m, 1 H), 2.67–2.71 (m, 1 H), 4.99–5.01 (m, 1 H), 5.08 (dq, *J*<sub>d</sub> = 17.0, *J*<sub>q</sub> = 1.7 Hz, 1 H), 5.74–5.77 (m, 1 H), 5.98–6.05 (m, 1 H), 6.16 (q, *J* = 0.9 Hz, 1 H). <sup>13</sup>C-NMR (CDCl<sub>3</sub>, 150 MHz)  $\delta$  13.8, 21.8, 29.2, 29.3, 30.1, 45.2, 88.2, 102.9, 115.4, 137.9, 139.2, 181.0. UV (methanol):  $\lambda_{\text{max}}$  (lg  $\epsilon$ /m<sup>2</sup> mol<sup>−1</sup>) 319 nm (3.14), 210 nm (3.05). Anal. Calcd for C<sub>12</sub>H<sub>17</sub>NOS<sub>2</sub> (255.40): C, 56.43; H, 6.71; N, 5.48; S, 25.11; Found: C, 56.48; H, 6.56; N, 5.68; S, 25.27.

**4.3.2 3-[*trans*-2-(Prop-2-en-1-yl)-cyclopent-1-yloxy]-4-methylthiazole-2(3*H*)-thione *trans*-(1a).** From *cis*-2-(prop-2-en-1-yl)-cyclopent-1-yl 4-toluenesulfonate (1.85 g, 6.60 mmol); reaction time: 1 hour at 45 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 1 (v/v), *R*<sub>f</sub> = 0.38. Yield: 1.13 g (4.42 mmol, 67%), yellow oil.<sup>36</sup> <sup>1</sup>H-NMR (CDCl<sub>3</sub>, 400 MHz)  $\delta$  1.28–1.37 (m, 1 H), 1.67–1.84 (m, 3 H), 1.86–1.93 (m, 1 H), 1.98–2.09 (m, 1 H), 2.21–2.30 (m, 2 H), 2.24 (d, *J* = 1.2 Hz, 3 H), 2.22–2.27 (m, 1 H), 4.97–5.05 (m, 2 H), 5.43–5.46 (m, 1 H), 5.78 (ddt, *J*<sub>d</sub> = 17.0, 10.2, *J*<sub>t</sub> = 6.8 Hz, 1 H), 6.16 (q, *J* = 1.4 Hz, 1 H). <sup>13</sup>C-NMR (CDCl<sub>3</sub>, 100 MHz)  $\delta$  14.1, 23.2, 30.4, 30.6, 37.6, 43.7,

92.1, 102.9, 116.3, 136.4, 138.8, 181.0. UV (methanol):  $\lambda_{\max}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 319 nm (3.17), 208 nm (3.09). Anal. Calcd for  $\text{C}_{12}\text{H}_{17}\text{NOS}_2$  (255.40): C, 56.43; H, 6.71; N, 5.48; S, 25.11; Found: C, 56.49; H, 6.85; N, 5.46; S, 24.96.

**4.3.3 3-[cis-2-(3-Methylbut-2-en-1-yl)-cyclopent-1-yloxy]-4-methylthiazole-2(3H)-thione cis-(1b).** From [*trans*-2-(3-methylbut-2-en-1-yl)-cyclopent-1-yl] 4-toluenesulfonate (2.48 g, 8.04 mmol); reaction time: 21 hours at 20 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 2 (v/v),  $R_f$  = 0.30. Yield: 1.49 g (5.26 mmol, 65%), colorless oil.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.59–1.76 (m, 3 H), 1.64 (s, 3 H), 1.71 (s, 3 H), 1.77–2.03 (m, 4 H), 2.18–2.30 (m, 1 H), 2.23 (d,  $J$  = 1.4 Hz, 3 H), 2.47–2.59 (m, 1 H), 5.33 (ddt,  $J_d$  = 7.9, 6.5,  $J_t$  = 1.5 Hz, 1 H), 5.72 (td,  $J_t$  = 4.5,  $J_d$  = 1.7 Hz, 1 H), 6.15 (d,  $J$  = 1.4 Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  13.8, 17.9, 21.9, 25.8, 27.1, 29.1, 29.4, 46.0, 88.5, 102.8, 123.5, 132.0, 139.2, 181.0. UV (methanol):  $\lambda_{\max}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 318 nm (3.14), 205 nm (3.16). Anal. Calcd for  $\text{C}_{14}\text{H}_{21}\text{NOS}_2$  (283.45): C, 59.32; H, 7.47; N, 4.94; S, 22.62; Found: C, 59.33; H, 7.38; N, 5.03; S, 22.47.

**4.3.4 3-[cis-2-(Prop-2-en-1-yl)-cyclohex-1-yloxy]-4-methylthiazole-2(3H)-thione cis-(1c).** From [*trans*-2-(prop-2-en-1-yl)-cyclohex-1-yl] 4-toluenesulfonate (6.30 g, 21.4 mmol); reaction time: 13 days at 40 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 2 (v/v),  $R_f$  = 0.28. Conversion 84%. Yield: 637 mg (2.36 mmol, 11%), colorless oil.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 600 MHz)  $\delta$  1.23–1.49 (m, 4 H), 1.54–1.83 (m, 4 H), 2.09–2.38 (m, 2 H), 2.25 (s, 3 H), 2.55–2.62 (m, 1 H), 4.99–5.08 (m, 2 H), 5.25–5.32 (m, 1 H), 5.73–5.84 (m, 1 H), 6.16 (d,  $J$  = 1.2 Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 150 MHz)  $\delta$  14.2, 20.4, 23.8, 26.1, 26.7, 30.5, 37.5, 85.2, 102.8, 116.1, 137.2, 139.1, 180.7. UV (methanol):  $\lambda_{\max}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 318 nm (3.18), 210 nm (3.12). Anal. Calcd for  $\text{C}_{13}\text{H}_{19}\text{NOS}_2$  (269.42): C, 57.96; H, 7.11; N, 5.20; S, 23.80; Found: C, 57.94; H, 7.34; N, 5.47; S, 23.73.

**4.3.5 3-[trans-2-(Prop-2-en-1-yl)-cyclohex-1-yloxy]-4-methylthiazole-2(3H)-thione trans-(1c).** From [*cis*-2-(prop-2-en-1-yl)-cyclohex-1-yl] 4-toluenesulfonate (1.63 g, 5.54 mmol); reaction time: 3 hours at 45 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 2 (v/v),  $R_f$  = 0.32. Yield: 412 mg (1.53 mmol, 28%), colorless oil, which crystallizes on standing at 20 °C. M.p. = 62–63 °C.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.03–1.13 (m, 1 H), 1.14–1.30 (m, 2 H), 1.32–1.44 (m, 1 H), 1.61–1.73 (m, 2 H), 1.73–1.84 (m, 2 H), 1.87–1.96 (m, 1 H), 2.13 (dt,  $J_d$  = 14.3,  $J_t$  = 8.3 Hz, 1 H), 2.24 (d,  $J$  = 1.2 Hz, 3 H), 2.83 (dddd,  $J$  = 14.1, 4.8, 3.4, 1.9 Hz, 1 H), 4.94–5.15 (m, 3 H), 5.79–5.97 (m, 1 H), 6.15 (d,  $J$  = 1.2 Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  14.1, 24.2, 25.0, 30.19, 30.23, 36.4, 41.8, 86.0, 102.8, 116.3, 136.8, 139.2, 180.7. UV (methanol):  $\lambda_{\max}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 318 nm (3.14), 211 nm (3.04). Anal. Calcd for  $\text{C}_{13}\text{H}_{19}\text{NOS}_2$  (269.42): C, 57.96; H, 7.11; N, 5.20; S, 23.80; Found: C, 58.16; H, 7.16; N, 5.19; S, 23.67.

**4.3.6 3-[cis-2-(Eth-1-en-1-yl)-cyclohex-1-ylmethoxy]-4-methylthiazole-2(3H)-thione cis-(1d).** From [*cis*-2-(eth-1-en-1-yl)-cyclohex-1-ylmethyl] 4-toluenesulfonate (1.50 g, 5.10 mmol); reaction time: 3 hours at 50 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 2 (v/v),  $R_f$  = 0.33. Yield: 1.03 g (3.81 mmol, 75%), colorless oil, which crystallizes on

standing at –18 °C. M.p. = 61–62 °C.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.34–1.65 (m, 6 H), 1.67–1.79 (m, 2 H), 2.16–2.22 (m, 1 H), 2.23 (d,  $J$  = 1.2 Hz, 3 H), 2.50 (dq,  $J_d$  = 8.3,  $J_q$  = 4.1 Hz, 1 H), 4.18 (dt,  $J_d$  = 23.0,  $J_t$  = 7.1 Hz, 2 H), 4.98–5.12 (m, 2 H), 6.02 (ddd,  $J$  = 17.1, 10.4, 8.4 Hz, 1 H), 6.14 (d,  $J$  = 1.2 Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  13.5, 22.2, 24.3, 25.5, 30.5, 38.5, 40.9, 78.2, 102.6, 115.8, 137.7, 138.4, 180.2. UV (methanol):  $\lambda_{\max}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 316 nm (3.19), 206 nm (3.11). Anal. Calcd for  $\text{C}_{13}\text{H}_{19}\text{NOS}_2$  (269.42): C, 57.96; H, 7.11; N, 5.20; S, 23.80; Found: C, 57.89; H, 6.94; N, 5.20; S, 23.44.

**4.3.7 3-[trans-2-(Eth-1-en-1-yl)-cyclohex-1-ylmethoxy]-4-methylthiazole-2(3H)-thione trans-(1d).** From [*trans*-2-(eth-1-en-1-yl)-cyclohex-1-ylmethyl] 4-toluenesulfonate (650 mg, 2.20 mmol); reaction time: 3 h at 40 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 2 (v/v),  $R_f$  = 0.33. Yield: 466 mg (1.73 mmol, 79%), yellow oil, which crystallizes from diethyl ether to afford colorless crystals. M.p. = 51–52 °C.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.14–1.41 (m, 4 H), 1.65–1.82 (m, 4 H), 1.84–1.96 (m, 1 H), 2.14–2.29 (m, 1 H), 2.24 (d,  $J$  = 1.0 Hz, 3 H), 4.10 (t,  $J$  = 7.6 Hz, 1 H), 4.41 (dd,  $J$  = 7.3, 3.4 Hz, 1 H), 4.97–5.04 (m, 2 H), 5.71 (ddd,  $J$  = 17.2, 10.0, 9.1 Hz, 1 H), 6.13 (d,  $J$  = 0.7 Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  13.5, 25.4, 25.6, 29.5, 33.5, 41.0, 44.6, 79.3, 102.6, 114.9, 137.7, 142.2, 180.3. UV (methanol):  $\lambda_{\max}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 317 nm (3.13), 208 nm (3.05). Anal. Calcd for  $\text{C}_{13}\text{H}_{19}\text{NOS}_2$  (269.42): C, 57.96; H, 7.11; N, 5.20; S, 23.80; Found: C, 57.92; H, 7.05; N, 5.20; S, 23.70.

**4.3.8 3-[cis-2-(2-Methylprop-1-en-1-yl)-cyclohex-1-ylmethoxy]-4-methylthiazole-2(3H)-thione cis-(1e).** From [*cis*-2-(2-methylprop-1-en-1-yl)-cyclohex-1-ylmethyl] 4-toluenesulfonate (1.06 g, 3.28 mmol); reaction time: 4 hours at 50 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 2 (v/v),  $R_f$  = 0.31. Yield: 761 mg (2.56 mmol, 78%), colorless oil, colorless crystals on standing at 20 °C. M.p. = 78 °C.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.29–1.56 (m, 6 H), 1.62 (d,  $J$  = 1.5 Hz, 3 H), 1.67–1.81 (m, 2 H), 1.71 (d,  $J$  = 1.5 Hz, 3 H), 2.11–2.25 (m, 1 H), 2.21 (d,  $J$  = 1.4 Hz, 3 H), 2.71–2.80 (m, 1 H), 4.15 (d,  $J$  = 6.8 Hz, 2 H), 5.35 (ddt,  $J_d$  = 9.8, 3.0,  $J_t$  = 1.5 Hz, 1 H), 6.13 (q,  $J$  = 1.4 Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  13.1, 18.0, 21.9, 24.8, 25.0, 26.2, 31.8, 34.3, 38.9, 78.9, 102.5, 123.5, 132.9, 137.8, 180.3. UV (methanol):  $\lambda_{\max}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 316 nm (3.10), 204 nm (3.18). Anal. Calcd for  $\text{C}_{15}\text{H}_{23}\text{NOS}_2$  (297.48): C, 60.56; H, 7.79; N, 4.71; S, 21.55; Found: C, 60.43; H, 7.68; N, 4.76; S, 21.43.

**4.3.9 3-[trans-2-(2-Methylprop-1-en-1-yl)-cyclohex-1-ylmethoxy]-4-methylthiazole-2(3H)-thione trans-(1e).** From [*trans*-2-(2-methylprop-1-en-1-yl)-cyclohex-1-ylmethyl] 4-toluenesulfonate (2.72 g, 8.44 mmol); reaction time: 2 hours at 45 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 2 (v/v),  $R_f$  = 0.31. Yield: 1.86 g (6.25 mmol, 74%), yellow oil, which was crystallized from ethyl acetate to afford a colorless solid. M.p. = 47–48 °C.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.01–1.15 (m, 1 H), 1.20–1.40 (m, 3 H), 1.54–1.86 (m, 4 H), 1.57 (d,  $J$  = 1.0 Hz, 3 H), 1.67 (d,  $J$  = 0.7 Hz, 3 H), 1.98–2.11 (m, 1 H), 2.14–2.29 (m, 1 H), 2.22 (d,  $J$  = 1.2 Hz, 3 H), 4.07 (t,  $J$  = 7.6 Hz, 1 H), 4.35 (dd,  $J$  = 7.3, 3.2 Hz, 1 H), 4.97 (dt,  $J_d$  = 9.3,  $J_t$  =

1.5 Hz, 1 H), 6.12 (d,  $J = 1.5$  Hz, 1 H).  $^{13}\text{C}$ -NMR ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  13.2, 18.1, 25.6, 25.7, 25.8, 29.9, 33.4, 38.7, 42.1, 79.5, 102.5, 128.8, 131.7, 137.8, 180.2. UV (methanol):  $\lambda_{\text{max}}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 317 nm (3.13), 209 nm (3.02). Anal. Calcd for  $\text{C}_{15}\text{H}_{23}\text{NOS}_2$  (297.48): C, 60.56; H, 7.79; N, 4.71; S, 21.55; Found: C, 60.41; H, 7.73; N, 4.74; S, 21.47.

**4.3.10 3-[2-(1-Methylenecyclohex-2-yl)-eth-1-yl-2-oxy]-4-methylthiazole-2(3H)-thione (1f).** From [2-(1-methylenecyclohex-2-yl)-ethyl] 4-toluenesulfonate (3.60 mg, 12.2 mmol); reaction time: 1 hour at 50 °C; the eluent used for chromatography: diethyl ether–pentane = 1 : 1 (v/v),  $R_f = 0.39$ . Yield: 2.57 g (9.54 mmol, 78%), yellow oil.  $^1\text{H}$ -NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.25–1.38 (m, 1 H), 1.42–1.55 (m, 2 H), 1.56–1.74 (m, 2 H), 1.76–1.89 (m, 2 H), 2.03 (ddd,  $J = 13.0, 8.5, 4.5$  Hz, 1 H), 2.14 (td,  $J_t = 14.1, J_d = 7.2$  Hz, 1 H), 2.20–2.39 (m, 2 H), 2.27 (d,  $J = 1.2$  Hz, 3 H), 4.38 (q,  $J = 7.3$  Hz, 1 H), 4.45 (q,  $J = 7.3$  Hz, 1 H), 4.60 (s, 1 H), 4.70 (s, 1 H), 6.15 (d,  $J = 1.2$  Hz, 1 H).  $^{13}\text{C}$ -NMR ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  13.4, 24.1, 28.6, 30.0, 34.0, 34.7, 39.4, 74.8, 102.6, 106.1, 137.7, 151.6, 180.3. UV (methanol):  $\lambda_{\text{max}}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 316 nm (3.18), 206 nm (3.10). Anal. Calcd for  $\text{C}_{13}\text{H}_{19}\text{NOS}_2$  (269.42): C, 57.96; H, 7.11; N, 5.20; S, 23.80. Found: C, 57.74; H, 7.12; N, 5.14; S, 23.93.

**4.3.11 3-[(1-Methylcyclohex-1-en-4-yl)-methoxy]-4-methylthiazole-2(3H)-thione (1g).** From [(1-methylcyclohex-1-en-4-yl)-methyl] 4-toluenesulfonate (4.20 g, 15.0 mmol); reaction time: 75 hours at 20 °C or 2 hours at 40 °C. Yield: 3.13 g (12.3 mmol, 82%), yellow oil, which was crystallized from methanol–ethyl acetate [2/1 (v/v)] to afford colorless crystals. M.p. 99–100 °C.  $^1\text{H}$ -NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.40–1.49 (m, 1 H), 1.63 (s, 3 H), 1.86–2.02 (m, 4 H), 2.09–2.25 (m, 2 H), 2.26 (d,  $J = 1.2$  Hz, 3 H), 4.22–4.32 (m, 2 H), 5.34–5.44 (m, 1 H), 6.16 (d,  $J = 1.2$  Hz, 1 H).  $^{13}\text{C}$ -NMR ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  13.4, 23.5, 25.5, 28.1, 29.0, 32.5, 74.8, 102.7, 119.1, 134.0, 137.7, 180.3. UV (methanol):  $\lambda_{\text{max}}$  ( $\lg \epsilon/\text{m}^2 \text{ mol}^{-1}$ ) 317 nm (3.11), 206 nm (3.06). Anal. #### 4.4 Alkoxy radical reactions

**4.4.1 Photochemical reactions.** A solution of 3-alkoxythiazolethione **1** (1.00 mmol,  $c_1^0 = 0.17 \text{ M}$ ) and  $\text{BrCCl}_3$  (10 mmol,  $c_{\text{BrCCl}_3}^0 = 1.67 \text{ M}$ ) in dry  $\text{C}_6\text{H}_6$  (6 mL) was photolyzed at  $\sim 25$  °C in a Rayonet® chamber reactor equipped with twelve 350 nm illuminants, until the starting material was completely consumed ( $\sim 30$  min, tlc). The solution was concentrated under reduced pressure (10 mbar, 40 °C) to leave an oil, which was purified by chromatography ( $\text{SiO}_2$ ).

**4.4.2 Thermal reactions.** A solution of 3-alkoxythiazolethione **1** (1.00 mmol,  $c_1^0 = 0.17 \text{ M}$ ),  $\text{BrCCl}_3$  (10 mmol,  $c_{\text{BrCCl}_3}^0 = 1.67 \text{ M}$ ), and AIBN (25 mol%) in dry  $\text{C}_6\text{H}_6$  (6 mL) was heated to 80 °C for 30 min. After complete consumption of **1** (tlc), the solvent was removed under reduced pressure (10 mbar, 40 °C) to leave a residue, which was purified by chromatography ( $\text{SiO}_2$ ).

## 4. Erzeugung und Reaktivität tertiärer O-Radikale

### 4.1 Zusammenfassung

*O*-tert-Alkylthiohydroxamate dienen als Quellen tertiärer Sauerstoff-Radikale und sind in Ausbeuten von bis zu 64 % aus tertiären *O*-Alkylisoharnstoffen und 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazol-2(3*H*)-thion synthetisierbar. Geschwindigkeitskonstanten  $k$  aus Umsetzungen der *O*-Radikalvorläufer in Gegenwart von Bromtrichlormethan spiegeln die hohe Reaktivität der tertiären *O*-Radikale in typischen Elementarreaktionen wider. Das 5-Phenyl-2-methylpent-2-oxyl-Radikal abstrahiert intramolekular ein  $\delta$ -H-Atom mit einer Geschwindigkeitskonstante von  $k^{\text{Subst}} = 10^7\text{--}10^8 \text{ s}^{-1}$ . Eine Größenordnung höher ist die Geschwindigkeitskonstante der 5-*exo*-Addition des 2-Phenyl-5-hexen-2-oxyl-Radikals ( $k^{5\text{-}exo} = 10^8\text{--}10^9 \text{ s}^{-1}$ ), dessen Ringschluss 2,5-*cis*-selektiv erfolgt. Der *exo*-spezifische Angriff des *p*-Chlorcumyloxy-Radikals an Norbornen erfolgt mit einer bimolekularen Geschwindigkeitskonstante von  $k^{\text{Add}} = 1 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ . Ursache der *exo*-spezifischen Addition an Norbornen sowie der 2,5-*cis*-Cyclisierung sind Torsionsspannungen in den *endo*- bzw. 2,5-*trans*-Übergangszuständen, was theoretische Analyseverfahren in diesem Zusammenhang verdeutlichen.

### 4.2 Wissenschaftlicher Hintergrund, Zielsetzung und Strategie

Um tertiäre *O*-Radikale in der organischen Synthesechemie routinemäßig einsetzen zu können, müssen deren Reaktivitäten und Selektivitäten bekannt sein. Fundamental sind hierbei Methoden zur Darstellung tertiärer *O*-Radikalvorläufer sowie zur Freisetzung entsprechender *O*-Radikale unter neutralen und nicht-oxidativen Bedingungen.<sup>[1-2]</sup> Versuche, etablierte Syntheseverfahren für primäre und sekundäre Thiohydroxamate<sup>[2-4]</sup> auf die Synthese tertiärer *O*-Ester zu übertragen, gelangen in frühen Arbeiten nur ansatzweise.<sup>[1,5]</sup> Erst durch Einsatz tertiärer *O*-Alkylisoharnstoffe<sup>[6-8]</sup> als Alkylierungsreagenzien konnten tertiäre *O*-Alkylthiohydroxamate<sup>[9]</sup> in Ausbeuten von bis zu 25 % hergestellt werden (Schema 4.1).<sup>[5,10]</sup> Analysen weiterer Reaktionsprodukte, die erlaubt hätten den Reaktionsverlauf genauer zu verstehen und die Reaktionsparameter ausbeutesteigernd anzupassen, blieben bisher aus. Um die Chemie tertiärer Alkoxy-Radikale aus Thiohydroxamsäure-*O*-ester weiterzuentwickeln, war das Ziel dieses Projektes, die Synthese tertiärer *O*-Alkylthio-

hydroxamate im präparativen Maßstab zu erschließen. Die dargestellten Zielmoleküle bilden dabei die Basis für konkurrenzkinetische Experimente im zweiten Teil der Studie, um mit Hilfe des Radikaluhr-Konzepts<sup>[11,12]</sup> Referenzreaktionen in der Sauerstoff-Radikalchemie kinetisch zu kalibrieren.

**Schema 4.1.** Veresterung tertiärer Alkohole durch *O*-Alkylisoharnstoffe.  $R^{tert} = CY_3$  mit  $Y =$  Alkyl, Aryl;  $HX =$  Carbon- oder Thiohydroxamsäure.

Für die vorliegenden Studie ergaben sich folgende Aufgabenstellungen, um Grundlagen für eine Anwendung tertiärer *O*-Radikale in der organischen Synthese zu schaffen.

- Prüfung der Isoharnstoff-Methode unter Verwendung von Thiohydroxamsäuren und tertiären Alkoholen auf Ausbeutensteigerungen und weitere Reaktionsprodukte.
- Nutzung der tertiären Thiohydroxamsäure-*O*-ester als *O*-Radikalquellen für die  $\delta$ -H-Abstraktion, 5-*exo-trig*-Cyclisierung und intermolekulare Addition.
- Formulierung von quantitativen Aussagen zur Reaktivität und Selektivität tertiärer *O*-Radikale mit Hilfe unimolekularer Vergleichsreaktionen und theoretischer Analyseverfahren.

## 4.3 Ergebnisse und Diskussion

### 4.3.1 Erzeugung und Eigenschaften tertiärer *O*-Alkylthiohydroxamate

*O*-Alkyl- und *O*-Cumylisoharnstoffe entstehen *in situ* aus den Alkoholen **1a–1f** und Diisopropylcarbodiimid (DIC) in Gegenwart katalytischer Mengen Kupfer(I)-chlorid. Mit 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazol-2(3*H*)-thion (MANTTOH, **2**) reagieren die Isoharnstoffe zu den tertiären *O*-Alkylthiohydroxamaten **3a–3f**. Zusätzliche Reaktions-

produkte sind Eliminierungsprodukte der Alkohole **1c–1f** (12–24 % pro Millimol MAnTTOH, nicht abgebildet) sowie die *N*-Oxide **4a–4f** (Tabelle 4.1).

**Tabelle 4.1.** Produkte und Ausbeuten der Umsetzung von 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazol-2(3*H*)-thion (**2**) mit *O*-Alkyl- und *O*-Cumylisoharnstoffen

Als blassgelbe oder farblose Feststoffe zeigen die Thiohydroxamsäuren **3a–3f** charakteristische UV/Vis-Absorptionsbanden bei 336–338 nm<sup>[13,14]</sup> und sind Ausgangsverbindungen für die Untersuchung der konkurrenzkinetischen Reaktionen. Mit Hilfe des entwickelten Verfahrens sind präparative Mengen an *O*-Alkylthiohydroxamaten (beispielsweise 1.5 g an **3f**) für die angestrebten Untersuchungen zugänglich.

### 4.3.2 Reaktivität und Selektivität tertiärer O-Radikale in Elementarreaktionen

#### (A) Homolytische Substitution

Thermische und photochemische Umsetzungen des *O*-(2-Methyl-5-phenylpentyl)-thiohydroxamats **3c** in Gegenwart von Bromtrichlormethan liefern als Hauptprodukt 2,2-Dimethyl-5-phenyltetrahydrofuran (**6**) (Tabelle 4.2). Als Nebenprodukte entstehen 2-Methyl-5-phenylpentan-2-ol (**1c**), Aceton (**7**) und das *in situ* gebildete  $\delta$ -Bromhydrin **5**, das nach spontaner HBr-Eliminierung zu Produkt **6** kondensiert. Aus dem Thiazolthion-Fragment bilden sich das Disulfid **8** und das Abfangprodukt 5-(4-Methoxyphenyl)-4-methyl-2-(trichlormethylsulfanyl)thiazol (**9**).

**Tabelle 4.2.** Produkte und Ausbeuten der Umsetzungen des 3-(5-Phenyl-2-methylpent-2-oxy)thiazol-2(3*H*)-thions **3c** mit Bromtrichlormethan

Eintrag	Bedingungen	Solvens	<b>1c</b> /%	<b>5</b> /%	<b>6</b> /%	<b>7</b> /%	<b>8</b> /%	<b>9</b> /%

2	$h\nu$ / $25^\circ\text{C}$	$\text{C}_6\text{D}_5\text{CF}_3$	23	– <sup>c</sup>	58	– <sup>b</sup>	34	27
3	AIBN / $80^\circ\text{C}$	$\text{C}_6\text{H}_6$	– <sup>b</sup>	– <sup>c</sup>	61	– <sup>b</sup>	– <sup>b</sup>	– <sup>b</sup>

<sup>a</sup> *In situ*-Messung ( $^1\text{H}$ -NMR) nach 2 h bei  $21^\circ\text{C}$ , interner Standard: Pentachlorbenzol, <sup>b</sup> nicht bestimmt, <sup>c</sup> nicht beobachtet.

Das Produktverhältnis  $[\mathbf{5}+\mathbf{6}]/[\mathbf{7}]$  spiegelt die relative Reaktivität zwischen Substitution und Fragmentierung wider (Schema 4.2). Mit der Geschwindigkeitskonstanten der Fragmentierung des *tert*-Butoxyl-Radikals ( $k^{\text{Frag}} = 2.0 \times 10^4 \text{ s}^{-1}$ ,  $25^\circ\text{C}$  in  $\text{C}_6\text{H}_6$ )<sup>[15]</sup> und einem Korrekturfaktor  $F_c$  (150–350)<sup>[16,17]</sup> für die bevorzugte Abspaltung eines Ethyl-Radikals anstelle eines

Methyl-Radikals, kann nach Gleichung 1 die Geschwindigkeitskonstante  $k^{\text{Subst}}_{\text{Ic}}$  berechnet werden. Sie beträgt für das Radikal **Ic**:  $k^{\text{Subst}}_{\text{Ic}} = 0.4\text{--}1.5 \times 10^8 \text{ s}^{-1}$  (25 °C, C<sub>6</sub>D<sub>6</sub>).

**Schema 4.2.** Konkurrenzkinetische Betrachtung der Substitution ( $k^{\text{Subst}}$ ) und Fragmentierung ( $k^{\text{Frag}}$ ) des Alkoxyl-Radikals **Ic** in Gegenwart von Bromtrichlormethan.

$$k^{\text{Subst}}_{\text{Ic}} = \frac{[5 + 6]}{[7]} k^{\text{Frag}} \times F_c \quad (\text{Gleichung 1})$$

### (B) Intramolekulare Addition

Die Bestrahlung von (2-Phenyl-5-hexen-2-oxyl)-thiazol-2(3*H*)-thion **3f** in Gegenwart von Bromtrichlormethan liefert als Hauptprodukte die diastereomeren,  $\beta$ -bromierten Tetrahydrofurane *cis*-**10** und *trans*-**10** (Schema 4.3). Weitere Reaktionsprodukte sind der tertiäre Alkohol **1f** und das Fragmentierungsprodukt Acetophenon (**11**).

**Schema 4.3.** Umsetzung von 2-Phenyl-5-hexen-2-yl-esters **3f** in Gegenwart von Bromtrichlormethan. Weitere Produkte: Disulfid **8** (30%) und Abfangprodukt **9** (45%).

Die Geschwindigkeitskonstanten des *cis*- und *trans*-Ringschlusses des Radikals **If** ergeben sich nach Gleichung 2 aus den Ausbeutenverhältnissen der Produkte *cis/trans*-**10** und **11** sowie der Geschwindigkeitskonstanten der Fragmentierung des 2-(4-Methylphenyl)-but-2-oxyl-Radikals zum (4-Methylphenyl)methylketon ( $k^{\text{Frag}} = 2.5 \times 10^8 \text{ s}^{-1}$ , 22 °C in CH<sub>3</sub>CN)<sup>[16]</sup> (Schema 4.4). Daraus ergibt sich:  $k^{5\text{-exo}(cis)}_{\text{If}} = 3 \times 10^9 \text{ s}^{-1}$  und  $k^{5\text{-exo}(trans)}_{\text{If}} = 1 \times 10^9 \text{ s}^{-1}$ .

$$k_{\text{If}}^{5\text{-exo}(cis)} = \frac{[cis\text{-}10]}{[11]} k^{\text{Frag}} \quad \text{bzw.} \quad k_{\text{If}}^{5\text{-exo}(trans)} = \frac{[trans\text{-}10]}{[11]} k^{\text{Frag}} \quad (\text{Gleichung 2})$$

**Schema 4.4.** Konkurrenzkinetische Betrachtung der intramolekularen Addition ( $k^{5\text{-exo}}$ ) und Fragmentierung ( $k^{\text{Frag}}$ ) des Alkoxy-Radikals **If** in Gegenwart von Bromtrichlormethan.

Das O-Radikal **If** cyclisiert 2,5-*cis*-selektiv, was anhand von Berechnungen<sup>[18]</sup> auf Basis des Twist-Modells in Kooperation mit Jens Hartung darauf zurückgeführt werden kann, dass für einen axial gebundenen Phenyl-Rest in paralleler Stellung zur Vinyl-Gruppe (*cis*- $2T^3$ ) geringere sterische Wechselwirkungen entstehen, als es für die axiale Anordnung der Methyl-Gruppe (*trans*- $2T_3$ ) der Fall ist (Abbildung 4.1). Übergangszustände, bei denen C3 und die Vinyl-Gruppe auf der gleichen Seite stehen (*cis*- $2T_3$  und *trans*- $2T^3$ ), sind aufgrund sterischer und ekliptischer Abstoßungen generell ungünstiger.

**Abbildung 4.1** Twist-Modell-Übergangszustände zur Beschreibung der Stereoselektivität in 5-*exo*-Cyclisierungen des O-Radikals **If**. Graue Kugel = Methyl-Gruppe.

## (C) Intermolekulare Addition

Bimolekulare Additionsreaktionen zwischen *tert*-Butyl- **3a**, Cumyl- **3d** oder *p*-Chlorcumyl-substituierten Thiohydroxamsäure-*O*-ester **3e** mit Norbornen (**12**) liefern nach photochemischer Aktivierung in Gegenwart von Bromtrichlormethan die 2-Brom-3-alkoxybicyclo[2.2.1]heptane (**14a**, **14d** und **14e**), die Ketone **7**, **11** und **13** sowie die Alkohole **1a**, **1d** und **1e** (Tabelle 4.3).<sup>[19,20]</sup> Norbornen (**12**) bietet dabei den Vorteil, dass dessen allylische H-Atome, aufgrund einer hohen Bindungsdissoziationsenergie ( $453.5 \pm 4 \text{ kJ/mol}$ )<sup>[21]</sup> des geometrisch gespannten Substrats, nicht abstrahiert werden können.

**Tabelle 4.3.** Produkte der intermolekularen Additionsreaktion der Thiohydroxamate **3a**, **3d** und **3e** mit Norbornen (**12**) in Gegenwart von Bromtrichlormethan

$\text{MAntTO-C(CH}_3)_2\text{-R} + \text{Norbornene} \xrightarrow[\text{h}\nu / 25^\circ\text{C}]{\text{BrCCl}_3, \text{CF}_3\text{C}_6\text{H}_5} \text{HO-C(CH}_3)_2\text{-R} + \text{R-C(=O)-CH}_3 + \text{Bicyclo[2.2.1]heptane-2-yl-O-C(CH}_3)_2\text{-R-Br}$

<sup>a</sup> nicht bestimmt, <sup>b</sup> 3-*exo*-Konfiguration für beide Stereoisomere, <sup>c</sup> nicht beteiligt, <sup>d</sup> GC-Analyse und Ausbeuten der Reaktionsprodukte.

Zur Abschätzung der bimolekularen Geschwindigkeitskonstanten dienen die Ausbeuten an **14e** und **13** bei verschiedenen Norbornenkonzentrationen (Tabelle 4.3, Eintrag 4–6, Schema 4.5). Unter Zugrundelegung der Fragmentierung von **1e** zu *p*-Chloracetophenon (**13**) ( $k^{\text{Frag}}\mathbf{1e} = 1 \times 10^6 \text{ s}^{-1}$ , 22 °C in CH<sub>3</sub>CN)<sup>[22]</sup> ergibt sich nach Gleichung 3 die Geschwindigkeitskonstante  $k^{\text{Add}}\mathbf{1e}$  der intermolekularen Addition von **1e** an Norbornen (**12**) in  $\alpha,\alpha,\alpha$ -Trifluortoluol bei 25 °C. Sie beträgt  $k^{\text{Add}}\mathbf{1e} = 1 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ .

**Schema 4.5.** Konkurrenzkinetische Betrachtung der Addition ( $k^{\text{Add}}$ ) und Fragmentierung ( $k^{\text{Frag}}$ ) des Radikals **le** in Gegenwart von Norbornen (**12**) und Bromtrichlormethan.

$$\frac{[\mathbf{14e}]}{[\mathbf{13}]} = \frac{k^{\text{Add}}_{\text{le}}}{k^{\text{Frag}}_{\text{le}}} [\mathbf{12}] \quad \Leftrightarrow \quad k^{\text{Add}}_{\text{le}} = \frac{[\mathbf{14e}]/[\mathbf{13}]}{[\mathbf{12}]} k^{\text{Frag}}_{\text{le}} \quad (\text{Gleichung 3})$$

Die tertiären O-Radikale **la**, **ld**, **le** addieren *exo*-spezifisch an Norbornen (**12**), ähnlich wie das sterisch weniger gehinderte Methoxyl-Radikal.<sup>[9,10,19]</sup> Der anschließende Bromeingang verläuft *trans*-selektiv (Abbildung 4.2).

**Abbildung 4.2.** Angriffsmöglichkeiten von Bromtrichlormethan am 2-Alkoxybicyclo[2.2.1]-heptan-3-yl-Radikal *exo-VI*. R = (CH<sub>3</sub>)<sub>3</sub>C, C<sub>6</sub>H<sub>5</sub>, *p*-Cl-C<sub>6</sub>H<sub>4</sub>.

Reaktions- ( $\Delta_{\text{R}}E$ ) und Aktivierungsenergien ( $\Delta E^{\ddagger}$ ) des *exo*- und *endo*-selektiven Angriffs tertiärer Alkoxy-Radikale an Norbornen (**12**) wurden in Kooperation mit Jens Hartung berechnet. Als Modell-Radikale dienten das *tert*-Butoxyl-Radikal **la** sowie zur Berücksichtigung sterischer Aspekte das Methoxyl-Radikal **lg**. Beide Radikale zeigen unabhängig von verwendeten Dichtefunktionalverfahren (B3LYP/6-31+G\*\*, BHandHLYP/6-31+G\*\* und BHandHLYP/6-311G\*\*) <sup>[23–27]</sup> einen stark exothermen Reaktionsverlauf mit vergleichbaren Barrieren für die *exo*- und *endo*-Addition an Norbornen (**12**) ( $\Delta_{\text{R}}E$ , Tabelle 4.4 exemplarisch für B3LYP/6-31+G\*\*), was gemäß dem Hammond-Postulat<sup>[28]</sup> kinetische Reaktionskontrolle und frühe, Edukt-ähnliche Übergangszustände impliziert.

**Tabelle 4.4.** Energien (B3LYP/6-31+G\*\*) der *exo*- und *endo*-Addition des Methoxyl- und des *tert*-Butoxyl-Radikals an Norbornen (**12**). **1a**: R = C(CH<sub>3</sub>)<sub>3</sub>, **1g**: R = CH<sub>3</sub>.

Eintrag	Radikal	$\Delta E^\ddagger / \text{kJ mol}^{-1}$	$\Delta_R E / \text{kJ mol}^{-1}$	$\Delta E_i^\ddagger / \text{kJ mol}^{-1}$	$\Delta E_{\text{TD}}^\ddagger / \text{kJ mol}^{-1}$
1	<i>exo</i> - <b>VIa</b>	14.8	-66.6	41.4	-26.6
2	<i>endo</i> - <b>VIa</b>	30.4	-67.0	59.2	-28.8
3	<i>exo</i> - <b>VIg</b>	7.7	-80.5	37.0	-29.3
4	<i>endo</i> - <b>VIg</b>	20.3	-78.8	52.3	-32.0

Die berechneten Reaktions- ( $\Delta_R E$ ) und Aktivierungsenergien ( $\Delta E^\ddagger$ ) erlauben unter Anwendung der Marcus-Theorie<sup>[28–30]</sup>, Aussagen zu intrinsischen Barrieren ( $\Delta E_i^\ddagger$ , Spannung / Sterik) einer thermoneutralen Reaktion (Gleichung 4) sowie zu thermodynamischen Barrieren ( $\Delta E_{\text{TD}}^\ddagger$ : Energien des Bindungsbruch bzw. der Bindungsbildung, Gleichung 5) für die intermolekularen *exo*- und *endo*-Additionen der Radikale **1a** und **1g** an Norbornen (**12**) zu formulieren (Tabelle 4.4).

$$\Delta E_i^\ddagger = \frac{\Delta E^\ddagger - \frac{\Delta_R E}{2} + \sqrt{(\Delta E^\ddagger)^2 - (\Delta_R E)(\Delta E^\ddagger)}}{2} \quad (\text{Gleichung 4})$$

$$\Delta E^\ddagger = \Delta E_i^\ddagger + \Delta E_{\text{TD}}^\ddagger \quad (\text{Gleichung 5})$$

Den Berechnungen zufolge ist die *exo*-Addition (*exo*-**VI**) beider Radikale (**1a**, **1g**) mit geringeren Spannungseffekten verbunden als die *endo*-Addition (*endo*-**VI**) ( $\Delta E_i^\ddagger$ , Tabelle 4.4). Thermodynamische Beiträge ( $\Delta E_{\text{TD}}^\ddagger$ ) und Angriffsmöglichkeiten beider Radikale sind vergleichbar, woraus folgt, dass intrinsische Effekte für die *exo*-Selektivität verantwortlich sind und mit zunehmender Sterik des Alkoxyl-Radikals steigen.

Der *exo*-Angriff des *O*-Radikals an die  $\pi$ -Bindung von **12** hat zur Folge, dass sich das Wasserstoffatom an C2 in die *endo*-Richtung bewegt, während sich das benachbarte olefinische Wasserstoffatom an C3 zum *O*-Radikal hin orientiert. Die daraus resultierende, synklinale Anordnung des Wasserstoffatoms an C2 und dem Brückenkopf-Wasserstoffatom an C1 ist mit geringeren Torsionsspannungen verbunden als es für einen *endo*-Angriff des *O*-Radikals der Fall wäre, der zu ekliptisch angeordneten Wasserstoffatomen an C1 und C2 führt (Abbildung 4.3).

**Abbildung 4.3.** *Exo*- und *endo*-Angriff eines tertiären *O*-Radikals an Norbornen (**12**). Weiße Kugeln: Brückenkopf H-Atome; schwarze Kugeln: olefinische H-Atome.

#### 4.4 Fazit & Ausblick

Der synthetische Zugang zu tertiären *O*-Alkylthiohydroxamten mit Hilfe der Isoharnstoff-Methode eröffnet Möglichkeiten, Reaktivitäten tertiärer *O*-Radikale genauer zu untersuchen. Die ersten zur Verfügung stehenden Daten zeigen unerwarteterweise, dass tertiäre *O*-Radikale noch reaktiver sind als primäre und sekundäre Analoga.

Überraschend sind insbesondere die Reaktivität und 2,5-*cis*-Selektivität des 2-Phenyl-5-hexen-2-oxyl-Radikals **If**, das in dieser Arbeit als Modell-Radikal für 5-*exo*-Cyclisierungen fungiert. In weiterführenden Arbeiten ist demnach die Ursache der Reaktivitätssteigerung im Vergleich zu primären und sekundären Derivaten von Bedeutung, aber auch die Allgemeingültigkeit der *cis*-Selektivität für Substituenten in Position 1. Beide Effekte lassen sich durch eine Substituentenvariation (z. B. CF<sub>3</sub>, CCl<sub>3</sub>, 4-Cl-C<sub>6</sub>H<sub>4</sub>, OMe, CO<sub>2</sub>Me, 4-MeO-C<sub>6</sub>H<sub>4</sub>) in direkter Nachbarschaft zum *O*-Radikal überprüfen.

## ABSTRACT

This study deals with the synthesis of *tert*-O-alkyl thiohydroxamates and their use as *tert*-alkoxyl radical precursors. *tert*-Alkoxyl radicals were applied in mechanistic studies to determine rate constants of (i) *p*-chlorocumyloxyl radical addition to bicyclo[2.2.1]heptene ( $k=1 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ ), (ii) 2-phenylhex-5-en-2-oxyl radical 5-*exo*-*trig*-cyclization ( $k^{\text{cis}}=3 \times 10^9 \text{ s}^{-1}$ ,  $k^{\text{trans}}=1 \times 10^9 \text{ s}^{-1}$ ), and (iii) 2-methyl-5-phenylpent-2-oxyl to 2-hydroxy-2-methyl-5-phenylpent-5-yl radical isomerization (1,5-H-atom shift;  $k=0.4\text{--}1.5 \times 10^8 \text{ s}^{-1}$ ). The reactions pose key steps in synthesis of 2,2,5-substituted tetrahydrofurans and 2-bromo-3-alkoxybicyclo[2.2.1]heptanes. Stereoselectivity in 5-*exo*-*trig* cyclization (2,5-*cis*) and intermolecular addition (*exo*/*endo*>99:1), originates from torsional strain in transition structures of alkoxyl radical reactions.

## 1. Introduction

In a given chemical environment, *tert*-alkoxyl radicals undergo fast unimolecular and bimolecular reactions, to leave diagnostic product mixtures. Chemical changes thereby follow distinct patterns of homolytic substitution ( $S_R$ ),  $\beta$ -C,C-homolysis ( $D_R$ ), and  $\pi$ -bond addition ( $A_R$ ), to mention the most important elementary reactions (Scheme 1).<sup>1–4</sup> It is this combination of reactivity and selectivity that explains the significance, *tert*-alkoxyl radicals have gained for elucidating reaction mechanisms in physical organic chemistry,<sup>5–7</sup> atmospheric science,<sup>8</sup> biochemistry,<sup>9–11</sup> and macromolecular chemistry.<sup>12,13</sup> With the advent of more selective progenitors, this interest, however, has partly shifted from mechanistic to more synthetically oriented studies. The desire to apply alkoxyl radicals in synthesis thereby comes from electrophilic properties of the radical oxygen, for example, in additions or homolytic substitutions. Alkoxyl radicals therefore add a component to organic synthesis that is not available from other intermediates.<sup>14–16</sup>

In an earlier study, we had shown that 3-alkoxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3H)-thiones (e.g., **1**) almost

quantitatively liberate alkoxyl radicals, if thermally or photochemically activated in the presence of a mediator.<sup>17</sup> Primary and secondary 3-alkoxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3H)-thiones are synthetically available in yields between 70 and 90%.<sup>17</sup> Attempts to prepare tertiary derivatives thereof from

alcohols or haloalkanes under solvolysis conditions, on the other hand, were not successful.<sup>18,19,24</sup> Strategies to apply Lewis-acids for more effective carbon electrophile-activation resulted in precipitation of thiohydroxamate complexes.<sup>20–22</sup> None of these complexes were receptive for O-alkylation.<sup>23</sup>

Since *tert*-alkoxyl radicals for synthetic applications remained difficult to generate,<sup>24</sup> we chose to develop a practical method for synthesis of 3-(*tert*-alkoxy)-thiazole-2(3*H*)-thiones **1a–f** (Fig. 1). To validate the performance of these compounds, we devised a project on synthesis of 2,2,5-substituted tetrahydrofurans and 2-bromo-3-alkoxybicyclo[2.2.1]heptanes from intra- and intermolecular alkoxy radical reactions. The compounds (vide infra) are derivatives of mono- and bicyclic secondary metabolites, pharmaceuticals, and pesticides, which sometimes are difficult to prepare in ionic reactions.<sup>25–27</sup> The most important results from the study show that synthesis of tertiary O-alkyl thiohydroxamates **1a–f** using a newly developed procedure is feasible in up to 64% yield. If activated, the molecules liberate *tert*-alkoxyl radicals, suitable for application in mechanistic and synthetic studies.

## 2. Results and interpretation

### 2.1. Tertiary 3-alkoxy-4-methylthiazole-2(3*H*)-thiones

The general strategy for O-alkylthiohydroxamate synthesis from thiohydroxamic acids requires selective alkylation at oxygen. The thiohydroxamic acid we chose in this study, 3-hydroxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3*H*)-thione (MANTTOH; **2**), has a remarkable affinity for substitution at oxygen instead of sulfur, if treated with an appropriate carbon electrophile.<sup>17</sup> To develop a synthetic method (**1a, 1b**; Section 2.1), investigate thermal stability (**1d**; Section 2.2), perform intramolecular reactions (**1c, 1f**; Section 2.3 And 2.4), and explore intermolecular alkoxy radical additions (**1a, 1d–e**; Section 2.5), we selected *tert*-alcohols **3a–f** as substrates to in situ generate carbon electrophiles.

In previous studies<sup>28,29</sup> we had discovered that O-*tert*-butyl-N,N-diisopropyl isourea<sup>30,31</sup> is a suitable reagent to use for developing a more efficient and general method for *tert*-O-alkylation of acid **2**. The isourea is available from *tert*-butanol **3a**, diisopropyl carbodiimide (DIC), and catalytic amounts of CuCl. We now report that slow addition of 5.5 equiv of the alkylation reagent to a CH<sub>2</sub>Cl<sub>2</sub>-solution of thiohydroxamic acid at 24 °C furnishes O-*tert*-butyl ester **1a** in 58–64% yield, besides *S*-*tert*-butyl derivative **4a** (25%).<sup>17,19,32</sup>

A change in solvent to DMF, fewer O-*tert*-butyl isourea equivalents, or lower reaction temperature (≤0 °C) reduces the yield of *tert*-butyl ester **1a**. Higher rates of O-*tert*-butyl isourea addition lead to formation of 1,2-bis-[5-(4-methoxyphenyl)-4-methylthiaz-3-yl]-

disulfane (**5**)<sup>33</sup> as additional product in up to 13% yield, whereas the yield of product **1a** decreases. Substitution of dicyclohexyl carbodiimide (DCC) for DIC (cf. Table 1, entry 1) was not successful in our hands (22% of **1a** under conditions used in Table 1, entry 1).

We furthermore used the in situ method to convert *tert*-amyl alcohol **3b**, 2-methyl-5-phenylpentan-2-ol (**3c**) (44–47%; Table 1, entries 2 and 3), and 2-arylalcohols **3d–f** (13–18%; Table 1, entries 4–6) into O-esters **1b–f**. Alkylsulfanythiazole N-oxides **4b–f**, but also alkenes, such as a 52/48-mixture of 2-methyl-5-phenylpent-1-ene and 2-methyl-5-phenylpent-2-ene (63–76% from **3c**),  $\alpha$ -methylstyrene (**6**) (39% from **3d**), *p*-chloro- $\alpha$ -methylstyrene (48% from **3e**), and a 63/37-mixture of 2-phenylhexa-1,5-diene and 5-phenylhexa-1,4-diene (24–38% from **3f**), were found as by-products. Since we had no head space equipment available, elimination products formed from **3a** and **3b** escaped analysis.

3-Alkoxythiazolethiones were obtained as colorless (**1c–f**) to pale yellow (**1a, 1b**) crystalline compounds that melted between 64 °C (**1c**) and 112 °C (**1a**). Electronic spectra of the thiazolethiones in solutions of EtOH showed a band located at  $\lambda$ =336–338 nm ( $\epsilon$  ~3.20–3.28 m<sup>2</sup> mol<sup>–1</sup>). This absorption is relevant for photochemical alkoxy radical generation from **1** (vide infra). The only NMR-spectroscopic aspect that deserves attention was a systematic absence of <sup>13</sup>C resonances from methyl groups attached to tertiary C-atoms, in the room temperature NMR spectra (except of **1a** and **1b**). Resonances of protons bound to such *unseen* carbons were broad. The reason behind this observation is a slow topomerization of substituents by N,O-rotation, as clarified via low temperature NMR-spectroscopy. For example, on cooling a solution of *p*-chlorocumyl ester **1e**, proton resonances of diastereotopic CH<sub>3</sub>-groups coalesce at –3 °C (referenced versus the MeOH NMR thermometer).<sup>34,35</sup> At –62 °C two base line separated signals at  $\delta$ <sub>H</sub> 1.89 and 2.11 are found, which correlate with sharp resonances at  $\delta$ <sub>C</sub> 22.0 and 31.9 ppm (HMQC). The barrier to N,O-rotation ( $\Delta G^\ddagger_{270}$ =53 kJ mol<sup>–1</sup>) that was calculated from the spectral information (Supplementary data) is, in view of an estimated precision of  $\pm$ 10%, close to the value of 44 kJ mol<sup>–1</sup> reported for ester **1d** (coalescence temperature: 276 K).<sup>18</sup>

In the crystal structure of **1e**, the *p*-chlorocumyl substituent is almost orthogonally offset from the heterocyclic plane [C2–N3–O1–C14=96.8(2)°] (Fig. 2). The N3–O1–C14 angle [116.0 (1)°] is widened and correlates with the value of ~116° that was predicted for *tert*-O-esters of **2** on the basis of a Taft–Dubois-relationship.<sup>18</sup> Distances N3–O1 [1.383(2) Å] and C2–S2 [1.659(3) Å] fit into a N–O/C=S-correlation derived from crystallographic data of ten MANTTors (Supplementary data). N,O-bond lengthening in this

Fig. 2. Ellipsoid graphic (50% probability) of 3-[2-(*p*-chlorophenyl)-2-propoxy]-thiazolethione **1e** in the solid state [293 K; H-atoms were drawn as circles of an arbitrary radius; the (*M*)-enantiomer was selected from the racemate in the unit cell; C2/c, Z=8].

product class, by introducing a sterically demanding substituent at oxygen, causes a shortening of the associated C=S bond. This structural responsiveness is stronger than for any other type of investigated thiohydroxamic acid, and explains why heterocycle **2** handles strain at oxygen so well.<sup>18</sup>

## 2.2. Thermal stability

*N*-Cumyloxythiazolethione **1d** (mp 108 °C) decomposes within 60 min, if heated in boiling toluene (Scheme 2). The reaction provides disulfide **5**,  $\alpha$ -methylstyrene **6**, acetophenone **7**, and thiolactam **8**.<sup>36</sup> The product spectrum suggests a Tschugaeff-type fragmentation, which should have also afforded MAnTTOH (**2**). To detect the latter, a color test was performed using Fe(II)-stained TLC-sheets. A green color thereby denotes Fe(II)/(bis)thiohydroxamate formation, and thus a positive analytical response. During thermal decomposition of **1d**, while continuously being checked with the spotting test, a transient positive analytical response (green spot) is found, however, only within a quite narrow time frame. Intensity and time-line of the photometric response correlate with results from a control, starting from thiohydroxamic acid **2** in boiling toluene. We stopped the reaction as no further acid **2** was detectable. Analysis of this solution (<sup>1</sup>H NMR, TLC) shows disulfide **5** as major product.

Scheme 2. Products of thermal 3-cumyloxythiazolethione decomposition.

## 2.3. Homolytic substitution

3-Alkoxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3*H*)-thiones liberate alkoxy radicals, if photochemically excited ( $\lambda=350$  nm, 25 °C) or heated in the presence of initiator AIBN. For both modes of activation C<sub>6</sub>H<sub>6</sub> or C<sub>6</sub>H<sub>5</sub>CF<sub>3</sub> are useful solvents, and BrCCl<sub>3</sub> the preferred mediator for conducting synthetic and mechanistic investigations.<sup>17</sup>

Photolysis of 3-(2-methyl-5-phenylpent-2-oxo)-thiazolethione **1c** and BrCCl<sub>3</sub> (*c*<sub>0</sub>=1.70 M) in a solution of C<sub>6</sub>D<sub>6</sub> furnishes alcohol **3c** (36%),  $\delta$ -bromohydrin **9** (41%), tetrahydrofuran **10** (22%), disulfide **5** (20%), and 5-(4-methoxyphenyl)-4-methyl-2-trichloromethylsulfanyl thiazole (**11**) (10%). Acetone (**12**) is obtained in 3–5% yield. A triplet at  $\delta=2.91$  (*J*=6.5 Hz) points to 3-bromo-1-phenylpropane formation. Signal overlap (<sup>1</sup>H NMR/GC) precluded quantitative analysis of this product. As the solution is allowed to rest for 48 h at 25 °C, bromoalcohol **9** is converted into additional 2,2-dimethyl-5-phenyl-tetrahydrofuran (**10**).<sup>37</sup> The latter compound was isolated from additional photochemical and thermally-induced experiments that used the same reactant concentrations, leading to similar yields of **10** (Table 2, entries 2 and 3).

From product analysis we conclude that the 2-methyl-5-phenylpent-2-oxyl radical (**1c**) is formed in photochemical and thermally-induced reactions starting from *N*-alkoxythiazolethione **1c** and BrCCl<sub>3</sub> (Scheme 3). A 1,5-H-atom shift transforms alkoxy radical **1c** into stabilized benzylic radical **II**. The latter abstracts a Br-atom from BrCCl<sub>3</sub> to give  $\delta$ -bromohydrin **9** and  $\cdot$ CCl<sub>3</sub>. Bromoalcohol **9** cyclizes upon standing to furnish tetrahydrofuran **10**. The total amount of 1,5-H-shifted intermediate **II** therefore relates to the combined yield of products **9** and **10** (63%). Since acetone (**12**) and 3-bromo-1-phenylpropane are formed as by-products, radical **1c** not only undergoes 1,5-H-atom shift **1c**  $\rightarrow$  **II** but also  $\beta$ -C-C-homolysis **1c**  $\rightarrow$  **III**+**12**. On the assumption that both reactions follow kinetic control, and Br-atom trapping by **II** is quantitative,<sup>17</sup> the ratio (**9**+**10**)/**12**=12.6–21.0 reflects relative reactivity of 1,5-H-atom shift versus  $\beta$ -C-C homolysis, that is,  $k^{S_{Hc}}/k^{D_{Hc}}$ . The rate constant for the  $\beta$ -fragmentation thereby can be approximated with the value for acetone liberation from *tert*-butoxyl radical fragmentation ( $k^{D_{Hc}}=2.0 \times 10^4$  s<sup>-1</sup>, for 25 °C in C<sub>6</sub>H<sub>6</sub>).<sup>38</sup> Since the ethyl radical forms by a factor of 150–350 faster from alkoxy radical  $\beta$ -C-C-fragmentation than the methyl radical,<sup>7,39</sup> a value of  $3.0 \times 10^6$  s<sup>-1</sup> was used as lower and  $7.0 \times 10^6$  s<sup>-1</sup> as upper limit for unknown  $k^{D_{Hc}}$ . The range obtained for  $k^{S_{Hc}}$  ( $0.4$ – $1.5 \times 10^8$  s<sup>-1</sup>) indicates that the 1,5-H-shift in *tert*-alkoxy radical **1c**, in spite of its steric encroachment near oxygen, is not slower than 1,5-H-shift in the 1-pentoxyl radical ( $k^{S_R}=2.7 \times 10^7$  s<sup>-1</sup> at 20 °C).<sup>40,41</sup>

Yields of alcohol **3c** between 23 and 36% show that an effective H-atom donor exists in reaction mixtures used for mechanistic experiments starting from **1c** (Table 2). Since benzylic radicals, for example, **II**, abstract a Br-atom from BrCCl<sub>3</sub> much faster than an H-atom from any known reductant, the issue of radical reduction is restricted to alkoxy radical **1c**. Although this chemistry does not interfere with the kinetic analysis outlined above and in the following sections, clarifying the nature of the reductant could also mean finding ways to inhibit unwanted alkoxy radical consumption. A control performed by photolyzing *tert*-butoxythiazolethione **1a** in solutions of C<sub>6</sub>D<sub>6</sub> or CCl<sub>4</sub>, provided *t*-BuOH, disulfide **5**, and at least one additional thiazole-derived product. Attempts, to separate the additional thiazole derivative failed. On the basis of signal integration it seems that a methyl group attached to thiazole probably is the unknown H-atom donor. Support for this interpretation comes from mass-balancing: the yield of alcohol **3c**, and of other alcohols obtained from 3-alkoxythiazolethiones, for example, **1c**–**f** (Sections 2.4 and 2.5), never exceeded the amount of thiazole-derived products that remained unidentified.

In previous work, we had explained formation of thiazole **11** via  $\cdot$ CCl<sub>3</sub>-addition to the thiocarbonyl group of a 3-alkoxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3*H*)-thione. This step is crucial for the mechanistic model, because it explains how  $\cdot$ CCl<sub>3</sub> is able to propagate the chain reaction.<sup>17</sup> The major thiazole-derived product from **1c**, however, was disulfide **5**. Controls performed by photolyzing CCl<sub>3</sub>-adduct **11** and BrCCl<sub>3</sub> in a solution of C<sub>6</sub>D<sub>6</sub> (for 45 min,  $\lambda=350$  nm, 25 °C) provided 58% of unspent material **11** and

**Table 2**Products formed from 3-(5-phenyl-2-methylpentoxy)-thiazolethione **1c** and BrCCl<sub>3</sub>

Entry	Conditions	Solvent	3c/%	9/%	10/%

<sup>a</sup> In situ-analysis (<sup>1</sup>H NMR) after 2 h; additional products: 20% of **5**, 10% of **11**, and 3–5% of acetone (**12**).<sup>b</sup> Product composition after work up; additional products: 17% of **5**, 27% of **11**.<sup>c</sup> Not determined.<sup>d</sup> Number in parentheses refer to yield prior to work up (<sup>1</sup>H NMR); yield of thiazole-derived products **5** and **11** not determined.**Scheme 3.** Proposed scheme for mechanistic discussion of 2-methyl-5-phenylpent-2-oxyl radical reactivity in the presence of BrCCl<sub>3</sub> (roman numbers refer to transients).

21% of disulfide **5**. Subjecting disulfide **5** and BrCCl<sub>3</sub> to the same conditions did not give **11**. This information shows that **11** cannot be precursor of the entire amount of **5**. In view of the strain imposed by *tert*-O-alkyl substitution (cf. Section 2.1),<sup>18</sup> it moreover seems that fragmentation of excited **1c** occurs in competition to the chain process, leading directly to O-radical **1c** and a thiyl radical, that is the monomer of disulfide **5**.

#### 2.4. Intramolecular addition

Photolysis of a solution of *N*-(2-phenylhex-5-en-2-oxo)-thiazolethione **1f** and BrCCl<sub>3</sub> (*c*<sub>0</sub>=0.83 M) provides 2-methyl-2-phenyl-5-bromomethyltetrahydrofuran (**13**),<sup>42</sup> acetophenone **7**, alkenol **3f**, disulfide **5**, and trichloromethylsulfanyl thiazole **11** (Scheme 4). 1-Phenylpent-4-en-1-one, a product of interest for the mechanistic discussion outlined below, was not detected using authentic reference (<sup>1</sup>H and <sup>13</sup>C NMR, GC). A modification of the reaction conducted in boiling C<sub>6</sub>H<sub>6</sub> using AIBN as initiator provided 63% of bromomethyltetrahydrofuran **13** (*cis/trans*=73:27), 8% of ketone **7**, and 21% of alkenol **3f**.

NOESY-spectra show a strong cross signal 5-H ↔ CH<sub>3</sub> for major bromocyclization product, which led to assignment of *cis*-configuration (i.e., *cis*-**13**). A 5-H ↔ C<sub>6</sub>H<sub>5</sub> correlation and the absence of a 5-H ↔ CH<sub>3</sub> cross peak was taken as evidence for *trans*-configuration of the minor component (i.e., *trans*-**13**).

The chemical nature of products obtained leads us to the conclusion that radical **If** is liberated from *N*-alkenoxythiazolethione **1f** and BrCCl<sub>3</sub>. Alkenoxyl radical **If** cyclizes stereoselectively (major: **If** → *cis*-**IV**), fragments (**If** → **7**+**V**), or abstracts a hydrogen atom (**If** → **3f**; vide supra). Since 5-*exo-trig* alkenoxyl radical addition to a terminal π-bond is irreversible and Br-atom abstraction by nucleophilic C-radicals from BrCCl<sub>3</sub> is virtually quantitative,<sup>17</sup> product ratios of **12** (for *cis*-**13**/7) and 3.8 (for *trans*-**13**/7; Scheme 4) reflect relative reactivity of cyclization versus β-C,C-homolysis for **If**, as expressed by  $k_{A_{K^{cis}}}/k_{D_{Hf}}$  and  $k_{A_{K^{trans}}}/k_{D_{Hf}}$  (Scheme 5). Approximation of the unknown value for  $k_{D_{Hf}}$  with the rate constant of 2-(4-methylphenyl)-but-2-oxyl radical fragmentation into *p*-tolylacetophenone and •C<sub>2</sub>H<sub>5</sub> ( $k_{D_R} = 2.5 \times 10^8 \text{ s}^{-1}$  in CH<sub>3</sub>CN at 22 °C),<sup>7</sup> provides  $k_{A_{K^{cis}}} = 3 \times 10^9 \text{ s}^{-1}$  and  $k_{A_{K^{trans}}} = 1 \times 10^9 \text{ s}^{-1}$ . Both values are slightly larger than references from 5-*exo-trig* cyclizations of structurally related secondary alkoxy radicals to double bonds of the same substitution pattern.<sup>43,44</sup>

**Scheme 5.** Reaction scheme for kinetic analysis of 2-phenylhex-5-en-2-oxyl radical reactions.**Scheme 4.** Products formed from 3-(2-phenylhex-5-en-2-oxo)-thiazolethione **1f** and BrCCl<sub>3</sub>.

**Fig. 3.** Transition structure model on the origin of 2,5-cis-stereoselectivity in cyclization **If** → **IV** (CIP hierarchy for assignment of relative configurations: Ph > CH<sub>3</sub>; the CH<sub>3</sub> substituent was drawn as a circle of an arbitrary radius for tutorial reasons; one enantiomer of the radical was arbitrarily chosen for presentation; arrows represent origin and effector of steric repulsion).

The observed 2,5-cis-stereoselectivity **If** → **cis-IV** for alkenoxyl radical cyclization is new: 1-alkyl-4-penten-1-oxyl radical cyclize 2,5-trans-selectivity, whereas 1-aryl-4-penten-1-oxyl radicals furnish a ~50/50-mixture of stereoisomers.<sup>43,44</sup> To explain stereoselectivity in this chemistry, a mnemonic device exists. It is applicable to kinetically controlled reactions and considers steric effects in transition structures.<sup>45</sup> Low in energy and thus significantly populated transition structures thereby derive from  $^2T^3$ - and  $^2T_3$  conformers of tetrahydrofuran. One of the C,O-bonds is at equilibrium distance of 1.47 Å and the second, that is, the newly formed bond, stretched to ~2.05 Å (Fig. 3).<sup>45</sup> This geometry takes stereoelectronic prerequisites for the O-radical addition to the  $\pi$ -bond and minimization of torsional strain, that is, a twist rather than an envelope conformer, into account. Since the inner carbon of the vinyl group is part of the three atom unit defining the twist plane, two bisectonal (*b*) arrangements for the =CH<sub>2</sub>-segment exist. The conformer having the vinyl terminus and the second next neighbor, that is, C3 on opposite sides is referred to as *exo*-bisectonal (*b<sup>exo</sup>*). The opposite orientation is called *endo*-bisectonal (*b<sup>endo</sup>*). In the *exo*-bisectonal form, which is the favored arrangement, H-atoms at positions 4 and 5 exhibit synclinal orientation. The *endo*-bisectonal arrangement, on the other hand, leads to an eclipsing of hydrogens at the two carbons thus increasing torsional strain of the conformers (Fig. 3). Since the phenyl group in benzyloxyl radicals favors co-planar alignment of aromatic plane and radical oxygen,<sup>46</sup> axial phenyl, and *exo*-bisectonal vinyl group orientation lead to no significant steric repulsion (Fig. 3, bottom right). In the *trans*- $^2T_3$ -configured transition structure, 1,3-interactions between vinyl and methyl groups arise that increase free energy of this conformer.<sup>45</sup> For a rapidly equilibrating system, selectivity of a reaction, according to transition state theory and the Curtin-Hammett-principle is given by a Boltzmann-distribution covering all relevant intermediates. For our simplified model this means that the lowest in energy conformer out of the ensemble of four intermediates displayed in Fig. 3, that is, transition structure *cis*- $^2T^3$ , is relevant for describing stereoselectivity of the 5-*exo*-ring closure of alkenoxyl radical **If**.

## 2.5. Intermolecular addition

**2.5.1. Synthetic and kinetic aspects.** Photochemical reactions of 3-alkoxythiazoethiones **1a**, **1d**, and **1e** in C<sub>6</sub>H<sub>5</sub>CF<sub>3</sub>-solutions

containing an excess of bicyclo[2.2.1]heptene (**14**) (*c*<sub>0</sub>=2.76 M) and BrCCl<sub>3</sub> (*c*<sub>0</sub>=278 mM) furnish 3-alkoxy-2-bromobicyclo[2.2.1]heptanes **16a**, **16d**, and **16e**. Yields of  $\beta$ -bromohydrin ethers grow along the series of transferred radicals *tert*-butoxyl (20%), *p*-chlorocumyloxyl (44%), and cumyloxyl (46%) (Table 4, entries 1–3). 1-Bromo-2-trichloromethylbicyclo[2.2.1]heptane **17**<sup>47,48</sup> and 2-chloro-1-thiazylsulfanylbicyclo[2.2.1]heptane **18** are formed as co-products. Trichloromethylsulfanyl thiazole **11** was surprisingly not found. Controls indicate that compound **11** is converted into adduct **18**, if photolyzed in an excess of olefin **14**. The mechanism of this reaction is under current investigations.

As the norbornene concentration is lowered from 0.21 M to 0.05 M, the fraction of addition product **16e** diminishes, whereas the amount of *p*-chloroacetophenone **15** grows (Table 5, entries 4–6). *p*-Chlorophenyl-2-propanol (**3e**) is obtained as additional product, presumably for reasons outlined in Section 2.3. Its yield supplemented the percentage of *p*-chlorocumyloxyl radical-derived products to 73–89%. A plot of ratios **16e**:**15** versus norbornene concentration was linear ( $[\mathbf{16e}]/[\mathbf{15}] = (9.33 \text{ M}^{-1})[\mathbf{14}]$ ;  $R^2 = 0.9997$ ). The slope, according to a kinetic model that takes irreversible *p*-chlorocumyloxyl radical fragmentation into ketone **15** and  $\cdot\text{CH}_3$ , and a kinetically controlled addition of *p*-chlorocumyloxyl radical **1e** to olefin **14** into account, corresponds to the ratio of  $k^{\text{A}_{\text{ite}}}/k^{\text{D}_{\text{ite}}}$  (Scheme 6 and Supplementary data). Approximation of  $k^{\text{D}_{\text{ite}}}$  for the reaction **1e** → **15** in C<sub>6</sub>H<sub>5</sub>CF<sub>3</sub> with the value determined in CH<sub>3</sub>CN ( $k^{\text{D}_{\text{ite}}} = 1 \times 10^6 \text{ s}^{-1}$  for 22 °C)<sup>6,49</sup> provides the rate constant  $k^{\text{A}_{\text{ite}}} = 1 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ . This value is one order of magnitude higher than an EPR-spectroscopically determined reference for *tert*-butoxyl radical addition to olefin **14** ( $k^{\text{A}_{\text{ita}}} = 1.1 \times 10^6 \text{ s}^{-1}$  for 27 °C).<sup>50</sup>

**2.5.2. Stereochemical aspects.** NOESY-cross signals 2-H ↔ 7-H and 3-H ↔ 6-H correlate with 3-*exo*-2-*endo*-configuration of major isomers of alkoxy radical addition products **16a**, **16d**, and **16e** (Table 3, entries 1–3). For the minor isomers, 3-H ↔ 2-H, 2-H ↔ 6-H, and 3-H ↔ 5-H NOESY-cross signals were found pointing to 3-*exo*-2-*exo*-configuration. Alkoxy radical addition to norbornene **14** therefore had appeared almost exclusively from the *exo*-side. Products of Br-atom trapping, i.e., **16a**, **16d**, and **16e**, show typical 2-*exo*/2-*endo*-ratios imposed by steric shielding of the *exo*-face of adduct radical **VI** by a sterically demanding substituent.<sup>47</sup>

Since the origin of the *exo*-stereoselectivity of alkoxy radical additions was not evident from the literature,<sup>47,51</sup> it was pursued using electronic structure methods.<sup>52,53</sup> To investigate the role of steric effects, the methoxyl radical (**1g**) was included into the study. Experimental stereoselectivities for addition of **1g** and the *tert*-butoxyl radical (**1a**) to olefin **14** are identical.<sup>15</sup> Based on method assessment for reproducing relative energies of radicals and transition structures from our own studies,<sup>45,54</sup> and from work of other groups,<sup>55,56</sup> we chose Becke's three parameter hybrid functional (B3LYP)<sup>57,58</sup> and Becke's half and half functional (BHandHLYP)<sup>59</sup> in combination with the 6-31+G\*\* basis set for conducting the computational analysis. The selected basis set includes diffuse and polarization wave functions, which are needed to adequately reproduce selectivities in radical additions. For exploring basis set dependence, the results were supplemented by BHandHLYP/6-311G\*\* calculations.<sup>56</sup>

Equilibrium structures of reactands **1a/g** and **14**, conformationally flexible products **Vla/g**, and transition structures *exo/endo*-**VIIa/g** were located on respective potential energy surfaces according to an established procedure.<sup>45</sup> Calculation of second derivatives (Hessian matrix) that lacked in negative eigenvalues or imaginary frequency by diagonalization, characterized computed structures of alkoxy radicals **1a/g**, olefin **14**, and bicyclic carbon radicals *exo/endo*-**Vla/g** as minima. Exactly one imaginary frequency *i* associated with an O,C2-stretching vibration shows that computed structures *exo*-**VIIa/g** and *endo*-**VIIa/g** are transition

structures with respect to C–O-bond formation (Table 4). Geometrical parameters of transition structures **VIIa/g** relevant for explaining the origin of *exo*-selectivity are listed in Table 4, zero-

point energy-corrected electronic energies ( $E$  for 0 K), Gibbs free energies ( $G$  for 298.15 K), and expectation values of the spin operator (for radicals) in the Supplementary data.

**Scheme 6.** Elementary reactions for kinetic analysis of intermolecular alkoxy radical addition to norbornene **14** via the *p*-chlorocumyloxy-‘radical clock’ (Ar=*p*-ClC<sub>6</sub>H<sub>4</sub>).

**Scheme 7.** Structure formulas and indexing of reactands for modeling alkoxy radical addition to norbornene **14** [R=C(CH<sub>3</sub>)<sub>3</sub> for **1a**, **VIa**, and **VIIa**; R=CH<sub>3</sub> for **1g**, **VIg**, and **VIIg**; see also Table 4 and the Supplementary data].

Computed zero-point vibrational energy-corrected electronic barriers ( $\Delta E^\ddagger$ ) were split into an intrinsic term ( $\Delta E_i^\ddagger$ ) and a thermodynamic component ( $\Delta E_{TD}^\ddagger$ ), according to Marcus-theory (Eqs. 1–3).<sup>60–62</sup> The intrinsic part reflects steric contributions in a thermoneutral, i.e., degenerated reaction having a barrier of  $\Delta E_i^\ddagger$  located at  $x^\ddagger=0.5$  on the reaction coordinate (Fig. 4). The thermodynamic part refers to energy terms originating from bond formation and bond breaking.

**Fig. 4.** Positioning of activation ( $\Delta E^\ddagger$ ) and intrinsic barrier ( $\Delta E_i^\ddagger$ ) according to Marcus-theory in  $E(x)$  profiles using harmonic potentials of equal curvature for initial ( $x=0$ ) and final state ( $x=1$ ).<sup>60,61</sup>

$$\Delta E_i^\ddagger = \frac{\Delta E^\ddagger - \frac{\Delta_R E}{2} + \sqrt{\left(\Delta E^\ddagger\right)^2 - (\Delta_R E)(\Delta E^\ddagger)}}{2} \quad (1)$$

$$x^\ddagger = \frac{1}{2} \left( 1 + \frac{\Delta_R E}{4\Delta E^\ddagger} \right) \quad (2)$$

$$\Delta E^\ddagger = \Delta E_i^\ddagger + \Delta E_{TD}^\ddagger \quad (3)$$

Calculated atomic distances, angles, and energy differences change gradually but not fundamentally, as the applied theoretical methods were varied (Tables 4 and 5). Independent from the method,

theory predicts strongly exothermic reactions and thus a high barrier for the reverse reaction, which means kinetic reaction control. Reaction energies for *exo*- and *endo*-additions of the radicals **1a** and **1g** are surprisingly similar. If compared to methoxyl radical additions, the *tert*-butoxyl radical additions, however, are consistently less exothermic. Location of the B3LYP-calculated transition structure *exo*-**VIIg** at  $x^\ddagger=-0.8$  shows that values obtained with this method should be treated with more care than the BHandHLYP data.<sup>56</sup> Calculated O...C2-distances of 2.0–2.2 Å and values for the  $x^\ddagger$  parameter between 0 and 0.3 (for exception vide supra) correlate with early transition structures on the reaction coordinates. Computed Gibbs free energies at 298.15 K favor transition structures *exo*-**VIIa/g** by 15–18 kJ over structures *endo*-**VIIa/g**, which leads to theoretical *exo/endo*-ratios of >99:1. These numbers agree in an excellent manner with the experimental findings.

The origin of the *exo*-selectivity in alkoxy radical additions to norbornene **14** in this model arises from subtle geometrical changes that occur in an early phase of the reaction. As the radical approaches the  $\pi$ -bond, the hydrogen at the attacked olefinic carbon moves backward. The vicinal olefinic hydrogen, on the other hand, shifts toward the incoming radical (cf. angles H1–C1–C2–H1 and H3–C3–C4–H4 in Table 4).<sup>63</sup> In transition structures *endo*-**VIIa/g** these changes lead to an eclipsing of hydrogens at the attacked carbon and the proximal bridgehead position. In the approach from the opposite side, that is, via intermediate *exo*-**VIIa/g**, the same hydrogens show synclinal orientation leading to less torsional strain (Table 4). These strain effects are furthermore evident from lower intrinsic barriers  $\Delta E_i^\ddagger$  for *exo*-additions, while thermodynamic contribution  $\Delta E_{TD}^\ddagger$  to the activation barrier remain for *exo/endo*-transition structures approximately similar.

In terms of steric effects, it becomes apparent from the computed numbers that *tert*-butoxyl radical additions were throughout the study associated with higher intrinsic barriers than methoxyl radical additions. These trends were attributed to a small but systematic size effect on alkoxy radical reactivity.

### 3. Concluding remarks

The strong affinity of 3-hydroxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3H)-thione (**2**) for alkylation at oxygen, in combination with the driving force of *O*-alkyl isoureas to transfer *tert*-alkyl groups to nucleophiles paved the road to synthesis of a new class of *tert*-alkoxy radical progenitors.<sup>18,64</sup> Although the chosen compounds (i.e., **1a–f**) pose a selection from our laboratory, we think that the method offers a general solution for converting tri-alkyl-substituted alcohols into *tert*-alkoxy radical precursors. Synthetic problems arose in esterifications of *tert*-2-aryllalkan-2-ols (e.g. **3d**), due to extensive elimination. Fortunately, an upscaling in such cases was feasible. This approach may be helpful in selected instances, to prepare sufficient material for conducting more specialized investigations using the thiohydroxamate method for *tert*-alkoxy radical generation.

Using *O*-alkyl thiohydroxamates **1a** and **1c–f**, we were for the first time able to prepare 2,2,5-substituted tetrahydrofurans (i.e., **10**, **13**) and 2-bromo-3-alkoxynorbornans (i.e., **16a**, **16d–e**) via an alkoxy radical pathway, which operates under mild and neutral conditions. The rate constants from the mechanistic part of the study show that *tert*-alkyl substitution near oxygen does not reduce alkoxy radical reactivity, at least in the investigated cases. However, we believe that true value of these data lies in the possibility they offer for more precisely setting up the selectivity requirement for new syntheses based on *tert*-alkoxy radical chemistry.

Bicyclo[2.2.1]heptene (**14**) was a rewarding alkene to explore intermolecular alkoxy radical additions. Its strained double bond and comparatively strong C,H-bonds offer favorable characteristics for the addition. Still we conclude from the kinetic data that intermolecular

alkoxyl radical additions have the potential to become more and more important, as the knowledge about this reaction increases.

As a final remark, we wish to address the aspect of stereoselectivity in *tert*-alkoxyl radical additions. It is well understood that stereoselectivity in cyclization is attainable via substrate control.<sup>45</sup> However, it seems worth to emphasize that stereoelectronic effects and geometrical changes within the  $\pi$ -bond, as a system approaches its transition structure, add another important component to this picture. With the wisdom of hindsight, it could have been anticipated that similar means for stereocontrol in intermolecular additions must exist, because the underlying reaction is the same. As we continue to seek for new stereoselective radical additions, the seemingly insignificant geometrical change in the early phase of the alkoxyl radical addition may be the most valuable hint, where to look.

#### 4. Experimental

##### 4.1. General

For general laboratory practice and instrumentation see Ref. 17 and the [Supplementary data](#).

##### 4.2. 3-(Alkoxy)-5-(4-methoxyphenyl)-4-methylthiazole-2(3H)-thiones

**4.2.1. General method for esterification of alcohols 3a–c.** CuCl (2 mol %) was added to a stirred solution of alcohol **3** (5.5 mmol) and DIC (5.5 mmol). Stirring was continued for 22–24 h at 20 °C. The resulting product was transferred into a syringe and was added over a period of 90 min in a dropwise manner at 24 °C (for **3a**) or at 0 °C (for **3b,c**) to a solution of 3-hydroxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3H)-thione (MANTOH; **2**) (1 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (2 mL). After complete addition, solids were removed by filtration to afford a clear solution, which was concentrated under reduced pressure. The remaining oil was purified by column chromatography (SiO<sub>2</sub>) using the eluent gradient (EG) specified below.

**4.2.2. General method for esterification of 2-arylalcohols 3d–f.** CuCl (2 mol %), alcohol **3** (2 mmol), and DIC (2 mmol) were stirred for 24–26 h at 20 °C as described in general method 4.2.1. The solution was added at –30 °C to a solution of 3-hydroxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3H)-thione (**2**) (1 mmol) and CH<sub>2</sub>Cl<sub>2</sub> (2 mL). The resulting mixture was worked up as specified in Section 4.2.1.

**4.2.3. Esterification of 2-methylpropan-2-ol (3a).** *tert*-Butanol **3a** (408 mg, 5.5 mmol) was treated as described in general method 4.2.1. EG: *tert*-butyl methyl ether/pentane=1:1 (v/v) → acetone/pentane=1:1 (v/v). 3-(2-Methylprop-2-oxy)-5-(4-methoxyphenyl)-4-methylthiazole-2(3H)-thione (**1a**).<sup>28</sup> Yield: 198 mg (64%), pale yellow solid, mp 114–115 °C. *R*<sub>f</sub>=0.45 for *tert*-butyl methyl ether/pentane=1:1 (v/v). UV (EtOH)  $\lambda_{\max}$  (log  $\epsilon$ /m<sup>2</sup> mol<sup>–1</sup>)=337 nm (3.25), 260 (2.89), 228 (3.13). Anal. ## 5. Heterocyclische O-(*tert*-Butyl)thiohydroxamate

### 5.1 Zusammenfassung

3-(*tert*-Butoxy)-4-methylthiazol-2(3*H*)-thione aus O-(*tert*-Butyl)isoharnstoff und 3-Hydroxy-4-methylthiazol-2(3*H*)-thionen sind stabile, kristalline Sauerstoff-Radikalvorläufer. Im Vergleich dazu, lagert das in Analogie hergestellte, 1-(*tert*-Butoxy)pyridin-2(1*H*)-thion spontan zum O-(*tert*-Butyl)pyridin-2-sulfenat um. Stabilitätsunterschiede beider Thiohydroxamat-Klassen lassen sich auf unterschiedlich starke N,O-Bindungen zurückführen, was N,O-Bindungsordnungen zwischen 1.3–1.4 in diesem Zusammenhang verdeutlichen. Drei überlagernde, partielle  $\pi$ -Bindungsanteile verschiedener Stärke, sind der MO-Theorie (Molekülorbital-Theorie) zufolge, dafür verantwortlich, dass die N,O-Bindungsordnung steigt. In 3-(*tert*-Butoxy)thiazol-2(3*H*)-thionen führt die Summe der  $\pi$ -Wechselwirkungen zu einer stärkeren Stabilisierung der N,O-Bindung und damit zu einer höheren Bindungsordnung als für das 1-(*tert*-Butoxy)pyridin-2(1*H*)-thion. Die photochemische Aktivierung der 3-(*tert*-Butoxy)-4-methylthiazol-2(3*H*)-thione liefert *tert*-Butoxyl-Radikale, die mit Hilfe der Elektronen-Spin-Resonanz-Spektroskopie und der intermolekularen Addition an Styrol, in Gegenwart von Bromtrichlormethan, nachgewiesen wurden.

### 5.2 Wissenschaftlicher Hintergrund, Zielsetzung und Strategie

Tertiäre Sauerstoff-Radikalvorläufer können aus 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazol-2(3*H*)-thion und einem tertiären O-Alkylisoharnstoff (Isoharnstoff-Methode) in bis zu 64 % Ausbeute hergestellt werden. In typischen Elementarreaktionen, wie inter- und intramolekularen Additionen oder Substitutionen, zeigen die aus den Thiohydroxamaten erzeugten tertiären O-Radikale, trotz größerer sterischer Belastung, eine vergleichbare oder sogar höhere Reaktivität als primäre und sekundäre Analoga (Kapitel 4).<sup>[1]</sup> Warum tertiäre 3-Alkoxythiazol-2(3*H*)-thione bis dato die einzige stabile Thiohydroxamat-Klasse zur Erzeugung tertiärer Sauerstoff-Radikale in der organischen Synthesechemie darstellen, soll in dieser Studie durch eine Kombination aus Theorie und Experiment untersucht werden.

Konkrete Ziele dieses Projektes lagen daher darin,

- *O*-(*tert*-Butyl)thiohydroxamate aus *O*-(*tert*-Butyl)-*N,N*-diisopropylisoharnstoff und weiteren cyclischen Thiohydroxamsäuren, wie 3-Hydroxy-4-methylthiazol-2(3*H*)-thion, 3-Hydroxy-4-methyl-5-(4-nitrophenyl)thiazol-2(3*H*)-thion und 1-Hydroxypyridin-2(1*H*)-thion herzustellen,
- anhand theoretischer Berechnungen (Dichtefunktional-Theorie und Møller-Plesset-Störungsrechnung 2. Ordnung) Aussagen zur Stabilität der tertiären Thiohydroxamate zu treffen und
- nachzuweisen, dass 3-(*tert*-Butoxy)thiazolthione durch photochemische Anregung *tert*-Butoxyl-Radikale erzeugen.

### 5.3 Ergebnisse und Diskussion

#### 5.3.1 Erzeugung und Eigenschaften von (*O*-*tert*-Butyl)thiohydroxamaten

**Thiohydroxamsäuren:** Die für diese Studie ausgewählten 3-Hydroxy-4-methylthiazol-2(3*H*)-thione **1a**<sup>[2]</sup> und **2a**<sup>[3]</sup> wurden nach literaturbekannten Verfahren hergestellt und repräsentieren die cyclischen Thiohydroxamsäuren mit der derzeit vielfältigsten Anwendungsbreite.<sup>[1,4,5]</sup> 3-Hydroxy-4-methyl-5-(4-nitrophenyl)thiazol-2(3*H*)-thion (**3a**) ist neu und aus 4-Nitrophenylacetone<sup>[6]</sup> in Anlehnung zur Synthese von MAnTTOH (**1a**)<sup>[2]</sup> darstellbar. Das 1-Hydroxypyridin-2(1*H*)-thion (**4a**) wurde von Mitarbeitern der Arbeitsgruppe für frühere Studien synthetisiert und der Allgemeinheit zur Verfügung gestellt (Abb. 5.1).

**Abbildung 5.1.** Thiohydroxamsäuren für die Herstellung der *O*-*tert*-Butylthiohydroxamate. MAnTTOH = 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazol-2(3*H*)-thion, An = Anisyl = 4-CH<sub>3</sub>OC<sub>6</sub>H<sub>4</sub>, MTTOH = 3-Hydroxy-4-methylthiazol-2(3*H*)-thion, MNPTTOH = 3-Hydroxy-4-methyl-5-(4-nitrophenyl)thiazol-2(3*H*)-thion, PTOH = 1-Hydroxypyridin-2(1*H*)-thion.

*3-(tert-Butoxy)-4-methylthiazol-2(3H)-thione*: In Analogie zur vorherigen Studie (Kapitel 4)<sup>[1]</sup>, in der die Thiohydroxamsäure **1a** über die Isoharnstoff-Methode zu den O-alkylierten **1b** und S-alkylierten Produkten **6b** führte (Tabelle 5.1, Eintrag 1), reagieren die 3-Hydroxy-4-methylthiazol-2(3H)-thione **2a–3a** in Gegenwart von *O*-(*tert*-Butyl)-*N,N*-diisopropylisoharnstoff<sup>[7,8]</sup> zu den Thiohydroxamsäure-*O*-estern **2b–3b**. Die *N*-Oxide **7b–8b** entstehen als Nebenprodukte der Alkylierung (Tabelle 5.1).

**Tabelle 5.1** Alkylierung der 3-Hydroxy-4-methylthiazol-2(3H)-thione **1a–3a** über die Isoharnstoff-Methode und physikalische Parameter der *O*-Alkylierungsprodukte **1b–3b**

Eintrag	R	<b>1b–3b</b> / %	$\lambda_{\max}$ <b>1b–3b</b> / nm	Schmp. <b>1b–3b</b> / °C	<b>6b–8b</b> / % <sup>e</sup>

<sup>a</sup> *in situ* aus 5.5 Äquivalente an *t*BuOH und Diisopropylcarbodiimid (DIC), <sup>b</sup> Ergebnis der vorherigen Studie (Kapitel 4), <sup>c</sup> aus 3 Experimenten, <sup>d</sup> aus 2 Experimenten, <sup>e</sup> repräsentativ aus einem Experiment isoliert.

Als farblose (**2b**) oder gelbe Feststoffe (**1b**, **3b**) zeigen die tertiären Ester die in der Tabelle 5.1 aufgeführten Schmelzpunkte. 3-(*tert*-Butoxy)-4-methyl-5-(4-nitrophenyl)thiazol-2(3H)-thion (MNPTTOtBu, **3b**) kristallisiert aus einer Diethylether/*n*-Pentan-Mischung (*v:v* = 1:1) in der monoklinen Raumgruppe *P*2<sub>1</sub>/*n* (Abbildung 5.2). Jede Elementarzelle verfügt dabei über vier Moleküle MNPTTOtBu (**3b**) entlang der zwei stereogenen Achsen [N3–O8] und [C5–*para*-Nitrophenyl-Gruppe]. Der *tert*-Butyl-Rest ist um 94°, die 4-Nitrophenyl-Gruppe um 26° aus der nahezu planaren Ebene des Heterocyclus herausgedreht. Der große

N3,O8,C9-Bindungswinkel von  $116.8(1)^\circ$  in **3b** zeigt, dass tertiäre 3-Alkoxythiazolthione sterischer Belastung bei O-Alkylierung entgegenwirken können. Für primäre und sekundäre O-Alkylthiohydroxamate ist der gleiche Winkel [N3, O8, C9] 4–5° kleiner.<sup>[9]</sup> Bindungslängen in **3b** (siehe Seite 107) entsprechen literaturbekannten Werten des 3-(Cumyloxyl)-5-(4-methoxyphenyl)-4-methyl-thiazol-2(3H)-thion.<sup>[9]</sup>

**Abbildung 5.2** Ellipsoidgrafik der Kristallstruktur von 3-(*tert*-Butoxy)-4-methyl-5-(4-nitrophenyl)thiazol-2(3H)-thion (**3b**) bei 150 K (50 % Wahrscheinlichkeit). Wasserstoffatome: willkürlicher Radius, Sauerstoff: rot, Stickstoff: blau, Schwefel: orange.

Die Kristallstruktur von 3-(*tert*-Butoxy)-4-methyl-5-(4-nitrophenyl)thiazol-2(3H)-thion (**3b**) zeigt unterschiedlich große *tert*-Butoxyl-Bindungswinkel zwischen den Atomen O8, C9 und den Kohlenstoff-Atomen C10–C12 [O8, C9, C10 =  $111.6^\circ$  / O8, C9, C11 =  $103.1^\circ$  / O8, C9, C12 =  $105.8^\circ$ ]. Studien strukturell verwandter Peroxide folgend, sind Winkel kleiner  $109^\circ$  das Resultat  $\pi$ -symmetrischer Wechselwirkungen zwischen dem  $\sigma(\text{O},\text{O})$ -Orbital und dem  $\sigma^*(\text{C},\text{C})$ -Orbital antiperiplanar oder antiklinal angeordneter C-C-Bindungen, die den O,C,C-Bindungswinkel reduzieren (Abbildung 5.3).<sup>[10,11]</sup>

**Abbildung 5.3** Molekülorbital-Modell zur Veranschaulichung der unterschiedlich großen *tert*-Butoxyl-Bindungswinkel O8, C9, C10–C12 in **3b** durch  $\pi$ -symmetrische Wechselwirkungen. NP = 4-Nitrophenyl.

Die *tert*-Butoxyl-Radikalvorläufer **1b–3b** lassen sich über diagnostische kernmagnetische Resonanzen der Thiocarbonyl-Gruppe ( $182 \pm 2$  ppm) sowie dem Singulett der *tert*-Butyl-Protonen ( $1.60 \pm 0.04$  ppm) charakterisieren. In Ethanol zeigen die Verbindungen **1b–3b** maximale UV/Vis-Absorptionsbanden, die auf spektroskopischen Überlagerungen von  $\pi \rightarrow \pi^*$  und  $n \rightarrow \pi^*$ -Anregungen des Alkenylsulfanylthiocarbonyl-Chromophors<sup>[12]</sup> beruhen. Das 4-Nitrophenyl-Derivat **3b** verfügt über eine zusätzliche Absorptionsbande bei 377 nm, die auf die Nitrophenyl-Gruppe<sup>[13]</sup> in Nachbarschaft zum Heterocyclus zurückzuführen ist (Tabelle 5.1). Infrarotabsorptionsspektren der Thiohydroxamate **1b–3b** in Acetonitril, die in Kooperation mit Manuel Zimmer aufgenommen wurden, besitzen die stärkste Bande bei  $1300 \pm 50$  cm<sup>-1</sup>, die zweifelsfrei der C,N-Streckschwingung zugeordnet wurde. Vier bis sechs weitere intensitätsschwache Banden im Fingerprintbereich ( $1200 - 850$  cm<sup>-1</sup>) kombinieren zu *exo*- und *endo*-cyclischen Gerüstschwingungen (C=S-/C,N-Streckschwingung; N,O-Biegeschwingung, C,H-Schwingungen). Diese Zuordnung gelang J. Hartung und M. Zimmer durch Dichtefunktional-Rechnungen (DFT-D3 / B3LYP / TZVP), theoretische Isotopensubstitutionen und durch Animation der berechneten und experimentell gemessenen Schwingungsspektren (siehe Kapitel 5.6 sowie Anhang C).

*1-(tert-Butoxy)pyridin-2(1H)-thion*: Die Umsetzung des 1-Hydroxypyridin-2(1H)-thions **4a** mit *O*-(*tert*-Butyl)-*N,N*-diisopropylisoharnstoff<sup>[7,8]</sup> zeigt im <sup>1</sup>H-NMR der Reaktionsmischung den (*tert*-Butyl)thiohydroxamsäure-*O*-ester **4b**<sup>[14]</sup> sowie das 2-(*tert*-Butyl)sulfanylpyridin *N*-Oxid (**9b**) (Schema 5.1).

**Schema 5.1.** Alkylierung des 1-Hydroxypyridin-2(1H)-thions (**4a**) (Isoharnstoff-Methode) und charakteristische kernmagnetische Resonanzen (<sup>13</sup>C) der Produkte **4b**, **9b** und **10b**. <sup>a</sup> *In situ* aus *t*BuOH (5.5 Äquivalente), DIC (5.5 Äquivalente), Cu(I)Cl (2 mol%).

Die Untersuchung ( $^1\text{H}$ -,  $^{13}\text{C}$ -NMR-Spektroskopie) der durch Säulenchromatographie erhaltenen Fraktion, in der das *O*-(*tert*-Butyl)thiohydroxamat **4b** erwartet wurde, zeigte Resonanzen, die dem Sulfenat **10b** zugeordnet wurden (Schema 5.1). Weder bei der Synthese der 5-Ring-Heterocyklen **1b–3b**, noch für das 1-(*tert*-Butoxy)pyridinthion **4b** fiel in früheren Arbeiten<sup>[1,14–16]</sup> eine derartige Umlagerung auf. Eine schnelle Zersetzung von **10b** verhindert bis dato die Isolierung und zweifelsfreie Charakterisierung der Verbindung. J. Hartung beobachtete in einem anderen Zusammenhang eine ähnliche Umlagerung des 1-Pentoxypyridin-2(1*H*)-thions (**4c**)<sup>[17]</sup> → **10c** (Schema 5.2). Ein präparativer Ansatz liefert das Sulfenat **10c** in analysenreiner Form und stützt durch Vergleich der  $^{13}\text{C}$ -NMR-Daten von **4b**, **9b**, **10b** mit **4c**, **9c**, **10c** die Umlagerung von **4b** → **10b**.

**Schema 5.2.** Photoreaktion des 1-Pentoxypyridin-2(1*H*)-thions (**4c**) zum *O*-Pentyl-2-pyridylsulfenat (**10c**) sowie *N*-Oxid **9c**, das bei der Herstellung von **4c**<sup>[17]</sup> entsteht mit signifikanten kernmagnetischen Resonanzen ( $^{13}\text{C}$ ).

### 5.3.2 Theoretische Berechnungen

*Hintergrund und Substrate:* Um Aussagen darüber treffen zu können, ob Regioselektivitäten bei der Veresterung der Thiohydroxamsäuren **1a–4a** mit Produktstabilitäten korrelieren und ob elektronische Wechselwirkungen zwischen dem Heterocyclen und dem *O*-Alkylrest auf konstitutionellen Unterschieden der *O*-Alkylpyridinthione und *O*-Alkylthiazolthione beruhen, wurden strukturelle Parameter und Bildungswärmen der *O*-(*tert*-Butyl)-Derivate **2b/4b**, der *S*-(*tert*-Butyl)-Verbindungen **7b/9b** sowie der *O*-(*tert*-Butyl)sulfenate **10b/11b** in Kooperation mit Jens Hartung berechnet. Zur Berücksichtigung sterischer Aspekte wurden die Rechnungen um die Methyl-Analoga der Thiazolthione **2d/7d/11d** sowie der Pyridinthione **4d/9d/10d** ergänzt.

*Methoden:* Die Berechnungen<sup>[18]</sup> erfolgten auf Grundlage der Dichtefunktionaltheorie (DFT: B3LYP<sup>[19,20]</sup> und BHandHLYP<sup>[21]</sup>) und Møller-Plesset-Störungsrechnung 2. Ord-

nung (MP2)<sup>[22–24]</sup> mit 6-31+G\*\*<sup>[25–27]</sup> als Basissatz.<sup>[28–31]</sup> Zur Methodenevaluierung wurden die Bindungslängen und –winkel der O-(*tert*-Butyl)thiohydroxamate **2b/2d**, **3b** und **4b/4d** mit den drei Methoden berechnet und mit den Kristallstrukturdaten von **3b**, dem 3-Cumyloxyl-4-methylthiazol-2(3*H*)-thion<sup>[32]</sup> und dem *trans*-(1-*tert*-Butyl)-cyclohex-4-yl-pyridin-2(1*H*)-thion<sup>[33]</sup> verglichen (siehe Seite 107). Der Vergleich zeigt, dass die B3LYP-Methode experimentelle N,O- und C,S-Bindungslängen am genauesten reproduziert, weshalb sie für alle folgenden Rechnungen verwendet wurde.

*Minimumstrukturen und Rotationsbarrieren der N,O-Bindung:* Zur Abwägung thermochemischer Trends wurden die energieärmsten Konformere der O-alkylierten- **2b/d**, **4b/d** und S-alkylierten-Verbindungen **7b/d**, **9b/d** sowie der Sulfenate **10b/d**, **11b/d** identifiziert. Dazu wurden die relativen Energien der genannten Verbindungen bei verschiedenen Torsionswinkeln  $\omega$  (in 15° Schritten) berechnet und korreliert (siehe Seite 110).

In globalen Minimumstrukturen ( $G_{(298)}^{min} = 0$  kJ/mol) **2b/d** und **4b/d** ist der O-(*tert*-Butyl)-Rest annähernd orthogonal ( $\omega_{C2,N,O,C9} = 90^\circ \pm 9^\circ$ , Tabelle 5.3) zum Heterocyclus angeordnet. Davon abweichende Diederwinkel  $\omega_{C2,N,O,C9}$  führen zu energiereichen Konformeren, mit synperiplanarer (syn,  $\omega_{C2,N,O,C9} = 0^\circ$ ) oder antiperiplanarer (anit,  $\omega_{C2,N,O,C9} = 180^\circ$ ) Konformation in lokalen Maxima. Die Differenz der freien Gibbs-Energien zwischen energetischem Minimum und Maximum beschreibt die Rotationsbarriere<sup>[34]</sup> des *tert*-Butyl-Rests um die rotationsgehinderte N,O-Bindung (Tabelle 5.3).

**Tabelle 5.3.** Berechnete (B3LYP/6-31+G\*\*// B3LYP/6-31+G\*\*) Torsionswinkel und Rotationsbarrieren der Thiazolthione **2b/d** und Pyridinthione **4b/d**. R = CH<sub>3</sub>, C(CH<sub>3</sub>)<sub>3</sub>.

Eintrag	Verbindung	$\omega_{C2,N,O,C9}^{min} / \text{Grad}^a$	$\Delta G_{(298)}^{syn} / \text{kJ mol}^{-1}^b$	$\Delta G_{(298)}^{anti} / \text{kJ mol}^{-1}^c$
1	MTTOtBu ( <b>2b</b> )	91.3	49.7	89.7
2	MTTOCH <sub>3</sub> ( <b>2d</b> )	83.4	38.5	65.3
3	PTOtBu ( <b>4b</b> )	99.9	63.5	44.4
4	PTOCH <sub>3</sub> ( <b>4d</b> )	83.9	44.4	35.1

<sup>a</sup>  $G_{(298)}^{min} = 0 \text{ kJ mol}^{-1}$ , <sup>b</sup>  $\Delta G_{(298)}^{syn} = G_{(298)}^{syn} - G_{(298)}^{min}$ , <sup>c</sup>  $\Delta G_{(298)}^{anti} = G_{(298)}^{anti} - G_{(298)}^{min}$

Minimumstrukturen der *S*-alkylierten Verbindungen **7d/b** und **9b** zeigen nahezu gauche Konformationen ( $\omega_{\text{N,C2,S7,C9}} = 63 \pm 5^\circ$ ). Nur das *S*-methylierte-Pyridinthion **9d** ist antiperiplanar ( $\omega_{\text{N,C2,S7,C9}} = 180^\circ$ ) angeordnet.<sup>[35,36]</sup> Gleichgewichtsstrukturen der Sulfenate besitzen Dach-Konformationen mit größeren Winkeln für die sterisch anspruchsvolleren *tert*-Butyl-Derivate **10b**, **11b** ( $\omega_{\text{C2,S7,O8,C9}} = 108^\circ$ ) im Vergleich zu den Methyl-Analoga **10d** und **11d** ( $\omega_{\text{C2,S7,O8,C9}} = 89^\circ \pm 2^\circ$ ).

*Relative Stabilitäten der Minimumstrukturen:* Für beide Thiohydroxamat-Klassen stellen die Sulfenate **10b/d** und **11b/d** die thermodynamisch stabilsten Produkte dar, gefolgt von den *S*-alkylierten Verbindungen **7b/d**, **9b/d** und den *O*-Alkyl-Derivaten **2b/d**, **4b/d**. Mit Ausnahme von **7b** sind dabei tertiäre Thiohydroxamate stabiler als primären *O*-Methylthiohydroxamate (Abbildung 5.4).

**Abbildung 5.4.** Berechnete (B3LYP/6-31+G\*\*//B3LYP/6-31+G\*\*) relative Energien der *O*-Alkylthiohydroxamate **2b/d**, **4b/d**, der *S*-Alkyl-Derivate **7b/d**, **9b/d** sowie der *O*-Alkyl-Sulfenate **10b/d**, **11b/d**.  $\text{CR}_3 = \text{CH}_3$  oder  $\text{C}(\text{CH}_3)_3$ . Relative Energien ( $E_{\text{rel}}$ ) der Thiazolthione (oben) beziehen sich auf andere Hyperflächen als die relative Energien ( $E_{\text{rel}}$ ) der Pyridinthione (unten).

Für das Pyridinthion stimmt die berechnete Stabilitätsreihe mit den experimentellen Beobachtungen überein. Thiazolthione liefern bei der Bildung primärer und sekundärer Radikalvorläufer nur selten *S*-alkylierte Produkte<sup>[37]</sup>, tertiäre Substrate stellen dabei eine Ausnahme dar und noch nie wurde die Bildung von Sulfenaten beobachtet. Demnach

beruhen Regioselektivitäten bei der Alkylierung von 3-Hydroxy-4-methylthiazol-2(3H)-thionen nicht auf thermodynamischen Effekten, sondern folgen kinetischen Faktoren. Die selektive O-Alkylierung des 3-Hydroxy-4-methyl-5-anisylthiazol-2(3H)-thions mit Methyltosylat sowie die selektive S-Alkylierung der gleichen Thiohydroxamsäure mit Methyljodid stützen die Interpretation zu den berechneten relativen Stabilitäten der Thiazolthion-abgeleiteten-Derivate **2**, **7** und **11**.<sup>[37]</sup>

*N,O-Bindungsordnung:* Die Bindungsstärke zwischen zwei Atomen lässt sich der Molekülorbital-Theorie folgend über Bindungsordnungen (BO)<sup>[38–39]</sup> beschreiben. Dazu werden experimentelle und theoretische N,O-Bindungslängen<sup>[40–42]</sup> gegen bekannte N,O-Bindungsordnungen aufgetragen und aus der resultierenden Geradensteigung die gesuchte Bindungsordnung bestimmt (siehe Anhang C, Seite 420). Für die O-(*tert*-Butyl)- und O-Methylthiohydroxamate **2b/d**, **3b**, **4b/d** ergeben sich daraus N,O-Bindungsordnungen von 1.3–1.4 und zeigen damit partielle  $\pi$ -Anteile der N,O-Bindung. Im direkten Vergleich haben *tert*-Butoxy-Derivate (z. B. **2b**: BO = 1.35) eine höhere Bindungsordnung als Methoxy-Derivate (z.B. **2d**: BO = 1.33) und Thiazolthione eine höhere Bindungsordnung als Pyridinthione (**4b**: BO = 1.33, **4d**: BO = 1.29).

*Ursache der partiellen  $\pi(N,O)$ -Bindung:* Gemäß der Natural Orbital Bond-Theorie (NOB-Theorie)<sup>[43–46]</sup> beruht die partielle  $\pi(N,O)$ -Bindung in den Thiohydroxamaten **2**, **3** und **4** auf unterschiedlich starken und überlagernden Wechselwirkungen mit  $\pi$ -Symmetrie, die die Bindungsordnung erhöhen ( $\pi^1_{N,O}$  und  $\pi^2_{N,O}$ ) oder senken ( $\pi^3_{N,O}$ ) (Abbildung 5.5).

**Abbildung 5.5.** Beschreibung der  $\pi(N,O)$ -Bindung in O-Alkylthiazolthionen basierend auf der NOB-Theorie<sup>[43–46]</sup> (X = C, H).  $\pi(N,O)$ -Bindung =  $\sum \pi^{1-3}_{N,O}$ .

Bindungsordnung erhöhend ist die Überlappung des nicht-bindenden p-Orbitals am Sauerstoff mit den  $\sigma^*_{N,C}$ -Orbitalen des Heterocycluses ( $\pi^1_{N,O}$ ) sowie die Überlappung des nicht-bindenden p-Orbitals am Stickstoff mit dem  $\sigma^*_{C,O}$ -Orbital ( $\pi^2_{N,O}$ ). Destabilisierend für die  $\pi(N,O)$ -Bindung und damit Bindungsordnung senkend sind Elektronen im  $\sigma^*_{N,O}$ -Orbital, die aus Überlappungen von  $\sigma$ -Elektronen des Heterocyclus und der Alkylgruppe ( $\pi^3_{N,O}$ ) stammen (Abbildung 5.5). In Summa überwiegen stabilisierende Effekte, wodurch die Bindungsordnung steigt. Für tertiäre Thiazolthione ist die partielle  $\pi(N,O)$ -Bindung stärker als für Methyl-Analoga oder für Pyridinthion-Derivate.

Überlappungen der  $\pi^1_{N,O}$ - und  $\pi^2_{N,O}$ -Wechselwirkungen sind für einen Diederwinkel  $\omega_{C2,N,O,C9} = 90^\circ$  maximal. Signifikante Abweichungen davon führen zur Schwächung der  $\pi(N,O)$ -Bindung und erhöhen die Rotationsbarriere. Demnach beeinflussen sterische (Thiocarbonyl-Gruppe, 4-CH<sub>3</sub>-Gruppe) und stereoelektronische Faktoren die Höhe der Rotationsbarriere in cyclischen Thiohydroxamaten. Da sich die Diederwinkeländerungen kaum auf die Energie der nicht-bindenden Orbitale am Stickstoff und Sauerstoff auswirken (NBO-Theorie), haben Coulomb-Abstoßungen zwischen den genannten Atomen keinen bedeutenden Beitrag zur Rotationsbarriere.<sup>[34]</sup> Strukturell äußern sich ungünstige Diederwinkel ( $\omega > 90^\circ < \omega$ ) in langen N,O-Abständen. Die Thiocarbonyl-Bindung reagiert darauf mit Verlängerung ( $\omega < 90^\circ$ ) oder Verkürzung ( $\omega > 90^\circ$ ) des C,S-Abstandes (Abbildung 5.6).

**Abbildung 5.6.** Diederwinkelabhängigkeit  $\omega_{C2,N,O,C9}$  von den N,O- und C2,N-Bindungslängen am Beispiel von 3-(*tert*-Butoxy)thiazolthion **2b**. (Atom-Nummerierung gemäß Abbildung 5.2).

*Einfluss des Bindungswinkels  $\alpha_{N,O,C9}$  auf die  $\pi(N,O)$ -Bindung:* Durch Zunahme des Thiohydroxamat-Bindungswinkels  $\alpha_{N,O,C9}$  ( $90^\circ \rightarrow 130^\circ$ , Abbildung 5.7) steigt der p-Anteil des nicht-bindenden Sauerstoff-Hybridorbitals (z.B. **2b**, 32 %  $\rightarrow$  55 %) und dessen Energie sowie die Fähigkeit Elektronen an die  $\sigma^*$ -Orbitale der Thiohydroxamat-Kerne abzugeben. Dadurch werden die beschriebenen  $\pi$ -symmetrischen-Wechselwirkungen der N,O-Bindung begünstigt. O-(tert-Butyl)thiohydroxamate besitzen aufgrund eines größeren sterischen Ausmaßes einen größeren Bindungswinkel  $\alpha_{N,O,C9}$  und damit einen stärkeren  $\pi$ -Bindungsanteil sowie eine kürzere N,O-Bindung als O-Methylthiohydroxamate (Abbildung 5.8). Da sich die  $\pi$ -Wechselwirkungen  $\pi^1_{N,O}$  und  $\pi^2_{N,O}$  stabilisierend auf das  $\pi^*$ -Orbital der Thiocarbonyl-Gruppe auswirken, reagiert sie auf große Bindungswinkel  $\alpha_{N,O,C9}$  und kurze N,O-Bindungen durch Verlängerung des C,S-Abstandes. Die Thiocarbonyl-Gruppe verhält sich demnach invers zu Änderungen der N,O-Bindung (siehe Seite 120).<sup>[9]</sup>

**Abbildung 5.7.** Bindungswinkelabhängigkeit von der Energie der  $\pi(N,O)$ -Bindung in heterocyclischen O-Alkylthiohydroxamaten.  $E_{\pi}(N,O) = \sum E_{\pi^{1-3}}(N,O)$  (siehe Abbildung 5.5).

**Abbildung 5.8.** Korrelation zwischen Thiohydroxamat-Bindungswinkel N, O, C9 und der N,O-Bindungslänge in heterocyclischen O-Alkylthiohydroxamaten.

Der beschriebene Stabilisierungsmechanismus ist für 3-Alkoxythiazol-2(3*H*)-thione effektiver als für 3-Alkoxy-pyridin-2(1*H*)-thione und verdeutlicht damit die höhere Stabilität der 5-Ring-Heterocyclen im Allgemeinen und bei der Herstellung tertiärer Derivate im Besonderen.

### 5.3.3 *tert*-Butoxyl-Radikaleinfang mit 5,5-Dimethylpyrrolidin-1-oxid und Styrol

5,5-Dimethylpyrrolidin-1-oxid (DMPO): Kurzlebige Alkoxyl-Radikale lassen sich mit DMPO<sup>[47]</sup> in persistente Radikale überführen und nachweisen (Elektronen-Spin-Resonanz-Spektroskopie).<sup>[48,49]</sup> Das Nitroxid-Radikal **12**<sup>[2,50–52]</sup> entsteht nach kurzer Bestrahlung (350 nm, 2 min) einer anaeroben, benzolischen Lösung der O-(*tert*-Butyl)thiohydroxamate **1b–3b** in Gegenwart von DMPO. Das Spektrum der gut untersuchten Verbindung **12** zeigt die bekannte Hyperfeinaufspaltung zum Stickstoffatom ( $a_N$ ), den Wasserstoffatomen in  $\beta$ - und  $\gamma$ -Position ( $a_H^\beta$  &  $a_H^\gamma$ ) sowie die chemische Verschiebung  $g$  (Tabelle 5.5).

**Tabelle 5.5** *tert*-Butoxyl-Radikaleinfang mit 5,5-Dimethyl-1-pyrrolidin *N*-oxid zum Nitroxid-Radikal **12** und dessen chemische Verschiebung ( $g$ ) sowie die Kopplungskonstanten ( $a$ ).

Eintrag	<b>1b–3b</b>	R	$g^a$	$a_N/G^a$	$a_H^\beta/G^a$	$a_H^\gamma/G^a$
1	<b>1b</b>	4-CH <sub>3</sub> O-C <sub>6</sub> H <sub>4</sub>	2.009	13.17	7.96	1.93
2	<b>2b</b>	H	2.009	13.15	7.94	– <sup>b</sup>
3	<b>3b</b>	4-NO <sub>2</sub> -C <sub>6</sub> H <sub>4</sub>	2.009	13.17	7.94	1.90

<sup>a</sup>  $H = 3478 \text{ G}$ ,  $\nu = 9.779 \times 10^9 \text{ Hz}$ , Modulation Amplitude = 0.0001 T, <sup>b</sup> nicht beobachtet.

*Styrol*: Die photochemische Umsetzung von 3-(*tert*-Butoxy)-4-methylthiazol-2(3*H*)-thion **2b** mit Styrol liefert in Gegenwart von Bromtrichlormethan regioselektiv 2-Brom-2-phenyl-1-(*tert*-butoxy)ethan (Schema 5.3).

**Schema 5.3.** Photochemische Umsetzung des *O*-(*tert*-Butyl)thiohydroxamats **2b** mit Styrol und Bromtrichlormethan.

## 5.4 Fazit & Ausblick

Die Existenz von *O*-(*tert*-Butyl)thiazol-2(3*H*)-thionen basiert auf Stabilitäten im Grundzustand. Günstige  $\pi$ -symmetrische Wechselwirkungen des Stickstoff- und Sauerstoffatoms mit dem Heterocyclus oder dem Alkyl-Rest führen, insbesondere für sterisch anspruchsvolle Reste, zu einer Erhöhung der N,O-Bindungsordnung auf 1.4 und damit zu einer sterischen Stabilisierung der tertiären Thiazolthione (MO- und NBO-Theorie). Für Pyridinthion-Derivate sind die stabilisierenden Effekte weniger effektiv und verdeutlichen damit die Schwierigkeiten, die mit der Synthese entsprechender Radikalvorläufer verbunden sind. Die beschriebene Stabilisierung von  $\sigma$ -Heteroatom-Heteroatom-Bindungen durch zusätzliche  $\pi$ -Wechselwirkungen benachbarter nicht-bindernder p- oder sp-Hybridorbitale mit Orbitalen angrenzender Atome kann in zukünftigen Studien Stabilitätsunterschiede zwischen beliebig kombinierten Heteroatomen, wie zum Beispiel Sauerstoff, Stickstoff, Chlor, Brom, Iod, Fluor, erklären. Für tertiäre 3-Alkoxythiazol-2(3*H*)-thione können die Grundzustandsstabilitäten dazu genutzt werden die Vielfalt tertiärer *O*-Alkylthiohydroxamate weiterzuentwickeln und nach Verlassen des Grundzustandes, durch photochemische oder thermische Aktivierung, den Einfluss polarer Effekte auf Stereoselektivitäten in Additionsreaktionen tertiärer *O*-Radikale zu untersuchen.

### Heterocyclic O-(*tert*-Butyl) Thiohydroxamates

Christine Schur, Manuel Zimmer, Harald Kelm, Markus Gerhards, and Jens Hartung

**Summary:** 3-Hydroxy-1,3-thiazole-2(3*H*)thiones react with *O*-(*tert*-butyl)-*N,N*-diisopropyl isourea to furnish heterocyclic *O*-(*tert*-butyl) thiohydroxamates in up to 64% yield. The compounds are stable crystalline solids, showing carbon-13 resonances for the thiocarbonyl group at  $183 \pm 1$  ppm, and vibrational combinations from the *O*-alkyl thiohydroxamate functional group, situated in the range between 950 and  $1300\text{ cm}^{-1}$ . 1-(*tert*-Butoxy)pyridine-2(1*H*)thione, prepared similarly, is a labile compound, quantitatively rearranging into *O*-(*tert*-butyl) pyridine-2-sulfenate. Differences in chemical behavior relate to N,O-bond strengths, as expressed for 3-(*tert*-butoxy)-1,3-thiazole-2(3*H*)thiones by a N,O-bond order of 1.4. Molecular orbital theory describes partial multiple bonding between nitrogen and oxygen as  $\sigma(\text{N,O})$ -bond in combination with three superimposed  $\pi(\text{N,O})$ -bonds of different strengths. Photoexciting 3-(*tert*-butoxy)thiazole-2(3*H*)thiones or adding an initiator radical to thiocarbonyl sulfur disconnects ground state stabilizing mechanisms, inducing homolytic breaking of N,O-bond. *tert*-Butoxyl radicals liberated from heterocyclic *O*-(*tert*-butyl) thiohydroxamates in photochemical experiments furnish spin-adducts, which were detected by electron spin resonance spectroscopy, or a 1-(*tert*-butoxy)-2-bromoalkane formed by intermolecularly adding to an alkene in the presence of bromotrichloromethane.

## Introduction

Oxygen radicals are reactive intermediates, transforming hydrocarbons with unique chemical reactivity and selectivity.<sup>[1–3]</sup> Hydrocarbon pollutants are broken down by oxygen radicals into lower alcohols and aldehydes, for being washed out from the atmosphere by rainfall.<sup>[4]</sup> Burning fossil fuels with dioxygen in combustion chambers oxidizes hydrocarbons via alkoxy radical mechanisms, liberating chemical energy for propelling vehicles.<sup>[5]</sup> In biochemistry, immune systems of mammals rely on hydroxyl radicals for destroying pathogenic germs.<sup>[6]</sup> Other oxygen radicals in combination with singlet dioxygen and oxygen radical anions transform nucleic acids, proteins, and secondary metabolites into xenobiotics, which contribute to develop symptoms of oxidative stress.<sup>[7]</sup> In biosynthesis, enzymes generate alkoxy radicals for constructing carbon-oxygen bonds in intramolecular additions with otherwise unattainable rate and selectivity.<sup>[3,8]</sup>

Mechanistically, most alkoxy radical reactions are additions, substitutions, and fragmentations.<sup>[3]</sup> Fragmentations are unimolecular processes, with rate constants

depending on solvent polarity, neighboring groups at reaction centers, and temperature. In a competition system, fragmentation serves as internal clock, for comparing rates of an unimolecular to a bimolecular process. In molar solutions of alkenes, rates of alkoxy radical fragmentation, addition, and substitution converge, yielding fingerprint mixtures of oxy-functionalized products.<sup>[9–10]</sup> Analyzing such mixtures allows to trace rates and concentration of involved reactants (Scheme 1).<sup>[11–13]</sup>

**Scheme 1** Products formed from alkoxy radical/alkene compositions (colorless circles denote carbon substituents, black circles a hydrogen, heteroatom group, or a carbon substituent).<sup>[11]</sup>

Synthesis with alkoxy radicals takes profit from complementary selectivity in additions to non-activated alkenes, when compared, for example, to ionic alkenol bromocyclization.<sup>[11,14,15]</sup> Trapping alkoxy radical addition products with a bromine atom donor affords  $\beta$ -bromohydrin ethers with unique radical selectivity, which is of interest for preparing bioactive compounds from the marine environment or for technical and synthetic use (Figure 1).<sup>[11, 16–18]</sup>

**Figure 1** Structure formulas of a naturally occurring tertiary  $\beta$ -bromohydrin ether (left: pantofuranoid E), and two bromohydrin ethers prepared from tertiary alkoxy radical reactions (center and right).<sup>[11,16,17]</sup>

Standard reagents for generating tertiary alkoxy radicals are alkanols,<sup>[19,20]</sup> *O*-alkyl nitrites,<sup>[21]</sup> alkyl hypohalites,<sup>[22]</sup> alkyl hydroperoxides,<sup>[23,24]</sup> dialkyl peroxides,<sup>[25–28]</sup> *O*-alkyl peresters,<sup>[29]</sup> *O*-alkyl benzene sulfenates,<sup>[30]</sup> *N*-alkoxyphthalimides,<sup>[31]</sup> and *O*-alkyl

thiohydroxamates (Scheme 2).<sup>[23,32]</sup> State-of-the-art synthesis with radicals occurs in pH-neutral non-oxidative environment and proceeds via linear chain reactions in the absence of tin hydride mediators.<sup>[33,34]</sup> Meeting these demands restricts the type of available precursors to the *O*-alkyl thiohydroxamates, which however are difficult to prepare from tertiary alcohols.<sup>[23]</sup> Synthesis of tertiary *O*-alkyl thiohydroxamates in attractive yields, at the moment, is developed only for a single thiohydroxamic acid (i.e. **1a**), using *O*-(*tert*-alkyl) isoureas as carbon electrophiles.<sup>[11,35–37]</sup> To broaden the scope for preparing *O*-(*tert*-butyl) esters, starting from heterocyclic thiohydroxamic acids having quite different chemical properties, we conducted the present experimental and theoretical investigation.

**Scheme 2** Approaches to synthesis of alkoxyl radical progenitors **II** starting from a hydrocarbon (top left, X = OH), a carbon electrophile (center left; Z = e.g. halogen, arylsulfonyloxy or *N,N*-dialkyl-*O*-isourey);  $\text{OX}^-$  = e.g. thiohydroxamate), or an alcohol [bottom left; XZ = e.g.  $\text{NOCl}$ ,  $t\text{BuOCl}$ ,  $\text{PhI}(\text{OAc})_2/\text{I}_2/\text{HgO}$ ], and conditions for liberating oxygen radical **I** (right).<sup>[23]</sup>

The major results from the study show that 3-(*tert*-butoxy)thiazole-2(3*H*)thiones prepared from underlying 3-hydroxythiazole-2(3*H*)thiones are stable compounds, while a derived pyridine-2(1*H*)thione quantitatively rearranges into a *O*-(*tert*-butyl) pyridine-sulfenate. Differences in chemical properties relate to N,O-bond strengths, as expressed for 3-(*tert*-butoxy)-1,3-thiazole-2(3*H*)thiones by a bond order of 1.4. Molecular orbital theory describes partial multiple bonding between nitrogen and oxygen as  $\sigma(\text{N,O})$ -bond in combination with three superimposed  $\pi(\text{N,O})$ -bonds of different strengths. Photoexciting a

3-(*tert*-butoxy)-1,3-thiazole-2(3*H*)thione, or adding an initiator radical to thiocarbonyl sulfur, disconnects ground state stabilizing effects and releases *tert*-butoxyl radicals, as exemplified by spin trapping experiments and intermolecular addition.

## Results and Interpretation

### 1 Thiohydroxamic acids

(i) *Significance of selected thiohydroxamic acids.* *O*-Alkyl derivatives of 3-hydroxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3*H*)thione (MAN<sub>T</sub>TOH) (**1a**), 3-hydroxy-4-methylthiazole-2(3*H*)thione (MTTOH) (**2a**), and 1-hydroxypyridine-2(1*H*)thione (PTOH) (**4a**) cover a spectrum of chemical properties, meeting most of the demands in synthetic and mechanistic alkoxy radical chemistry.<sup>[23,38,39]</sup> Colorless *O*-esters of 3-hydroxythiazolethione **2a** and pale-yellow *O*-alkyl derivatives of *p*-methoxyphenyl-substituted acid **1a** withstand acidic and basic conditions, allowing final chemical modifications of the ester side chain, for finalizing syntheses of more complex alkoxy radical progenitors. Compounds of this kind are stable when stored, and quantitatively liberate alkoxy radicals within thirty minutes when heated or being photolyzed. Alkoxy radical reactions involving 1-(alkoxy)pyridine-2(1*H*)thiones (i.e. esters of **1a**) are complete with a minute or less. Depending on the chemical nature of the *O*-alkyl group, the compounds may be stored or decompose with hour.<sup>[38,40]</sup> For generating alkoxy radicals from a compound with storage stability, by illuminating with blue light emitting diode,<sup>[41]</sup> we developed 3-hydroxy-4-methyl-5-(4-nitrophenyl)thiazole-2(3*H*)thione (MNPTTOH) (**3a**), and introduce this compound here for the first time (Figure 2).

**Figure 2** Structure formulas of cyclic thiohydroxamic acids **1a–4a** used for preparing *O*-(*tert*-butyl) esters {An = *para*-anisyl [*p*-C<sub>6</sub>H<sub>4</sub>(OCH<sub>3</sub>)]; NP = *para*-nitrophenyl [*p*-C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)]}.

(ii) *Synthesis of heterocyclic thiohydroxamic acids.* Synthesis 3-hydroxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3*H*)thione (MAN<sub>T</sub>TOH) (**1a**) and *p*-nitrophenyl-derivative MNPTTOH (**3a**) (Scheme 3) followed an adapted procedure, developed for preparing 3-

hydroxy-4-methylthiazolethione **2a** (MTTOH) by Kretzschmar and Barton.<sup>[42–44]</sup> 1-Hydroxy-pyridinethione **4a** (PTOH) precipitates by adding one equivalent of hydrochloric acid to an aqueous solution sodium omadine<sup>TM</sup>.<sup>[45]</sup>

**Scheme 3** Synthesis of 3-hydroxy-4-methyl-5-(4-nitrophenyl)thiazole-2(3H)thione (**3a**).

Thiohydroxamic acids are colorless (**2a**, **4a**) to yellow (**1a**, **3a**) solids, dissolving in lower alkanols, dimethyl sulfoxide, or aqueous alkali hydroxide. Hydroxyl groups give rise to broad proton-NMR resonances between 9.0 and 12.5 ppm in solutions of deuteriochloroform or dimethyl sulfoxide. Thiocarbonyl carbons show characteristic resonances at  $173 \pm 4$  ppm.

## 2. Preparation, spectroscopic properties, and structural aspects of 3-alkoxy-4-methylthiazole-2(3H)thiones

(i) *General remarks on atom numbering for structural discussions.* Numbering of atoms within heterocycles follows the Hantzsch-Widman notation (for examples, see Figures 4 and 6).<sup>[46,47]</sup> Atoms relevant for structural and spectroscopic discussions, attached to heterocycles, such as the thione sulfur (S7), thiohydroxamate oxygen (O8), ester carbon (C9), and carbons bound to C9 (C10–12), are for tutorial reasons numbered chronologically.

(ii) *The alkylation reagent.* O-(tert-Butyl)-N,N-diisopropyl isourea (**5**) is an unstable liquid prepared from *tert*-butanol and N,N-diisopropylcarbodiimide (DIC) in a copper (I)-chloride-catalyzed reaction at room temperature ( $20 \pm 2$  °C) (Scheme 4).<sup>[48]</sup> The yield of isourea **5** under such conditions goes through a maximum of 61 % after ~ 24 hours. Beyond this point of time, the fraction of decomposition product diisopropyl urea (DIU) increases.

**Scheme 4.** Synthesis of *O*-(*tert*-butyl)-*N,N*-diisopropyl isourea.<sup>[48]</sup>

The proton-NMR spectrum of *O*-(*tert*-butyl)-*N,N*-diisopropyl isourea (**5**) recorded in solution of deuteriochloroform displays a singlet at 1.47 ppm for *tert*-butyl protons, two sets of septets at 3.13 ppm and 3.66 ppm, and two doublets at 1.04 and 1.08 ppm for the two isopropyl groups.<sup>[49]</sup> Resonances of DIU in deuteriochloroform show chemical shifts of 5.49 ppm (d) for the amine proton, and at 1.00 (d), 3.62 (sept), and 3.64 (sept) for isopropyl protons.

(iii) *Thiazole-derived O*-(*tert*-butyl) thiohydroxamates. *O*-(*tert*-Butyl) thiohydroxamate **1b** forms in average yields of 61±3% ( $n = 3$ ), by adding a 5.5-molar excess of *O*-(*tert*-butyl) isourea **5** at room temperature to a solution of MAN<sub>2</sub>TOH (**1a**) in dichloromethane (Table 1, entry 1).<sup>[11]</sup> All parameter variations we undertook for raising efficiency of the synthesis, by decreasing reaction temperature, changing solvent to dimethylformamide, modifying isourea concentration and aliquots, increased the fraction of DIU and lowered yields of ester **1b**.<sup>[50]</sup> Treating MTTOH (**2a**) and MNPTTOH (**3a**) with isourea **5**, as specified for MAN<sub>2</sub>TOH (**1a**), provides *tert*-butyl thiohydroxamates **2b** and **3b** in 39–55% yields (Table 1, entries 2–3).

Thiazole-derived *tert*-butyl thiohydroxamates are colorless (**2b**) to yellow solids (**1b**, **3b**), melting at 57 °C (**2b**), 115 °C (**1b**), and 153 °C (**3b**). The compounds are stable when stored at room temperature in standard glassware. When heated to 130 °C at a pressure of  $8 \times 10^{-3}$  millibars, 3-(*tert*-butoxy)-4-methylthiazolethione (MTTO<sub>t</sub>Bu) (**2b**), gradually darkens and finally turns black without showing any signs of boiling. From this information we concluded that distilling is no alternative to chromatography for purifying *tert*-butyl esters **1b–3b**. A proton NMR-spectrum recorded from the black material showed almost exclusively resonances of ester **2b**.

**Table 1** Products formed from 4-methylthiazole-derived thiohydroxamates **1a–3a** and *O*-(*tert*-butyl)-*N,N*-diisopropyl isourea (**5**).

	<b>1a–3a</b>	<b>5</b>

<sup>a</sup> Isolated from one representative experiment. <sup>b</sup> 3 Experiments. <sup>c</sup> 2 Experiments.

(iv) *S*-Alkylation. *S*-(*tert*-Butyl) thiohydroximates **6b–8b** form as side products in 17–25% yields from reactions between acids **1a–3a** and *O*-(*tert*-butyl) isourea **5**. The products are colorless crystalline solids, quantitatively separating from *O*-esters **1b–3b** during chromatography, given ratio-of-fronts close to zero for the combination of ether/alkane-mixtures as eluents, and silica gel as stationary phase.

(v) *Electronic spectra of 3-(tert-butoxy)thiazolethiones*. *O*-(*tert*-Butyl) esters **1b–3b** absorb near UV/light, with maxima gradually shifting in solutions of methanol from 319 nanometers for **2b** via 337 for **1b** to 377 nanometers for **3b**.

According to theory, the lowest in energy electronic absorption band of 3-(alkoxy)thiazole-2(3*H*)thiones arises from  $\pi \rightarrow \pi^*$ - and  $n \rightarrow \pi^*$ -transitions between orbitals involving predominantly the heterocyclic alkenylsulfanylthiocarbonyl chromophore.<sup>[38]</sup> The singlet excited state rapidly converts into a triplet, which is antibonding for the nitrogen-oxygen bond.<sup>[51]</sup>

The absorption band at 377 nanometers in ester **3b**, we assigned to  $\pi \rightarrow \pi^*$ -transitions between orbitals of the *p*-nitrophenyl group. The band is shifted 37 nanometers from the nitrobenzene band ( $\lambda_{\text{max}} = 340 \text{ nm}$ ), due to electron conjugation within in ester **3b**.<sup>[52]</sup> The band located at 324 nanometers, in this interpretation, is the thioazole-2(3*H*)thione band, relevant for homolytically breaking the N,O bond.<sup>[38,53]</sup>

(vi) *Proton-NMR and carbon-13 chemical shifts of O-tert-butyl esters.* Carbon-13 NMR-resonances suitable for identifying products of thiohydroxamate O-alkylation originate from thiocarbonyl carbon C2 ( $183 \pm 1$  ppm) and heterocyclic enamine carbon C5 ( $117 \pm 3$  ppm for **1a** and **3a**; 102.5 for **2a**). The half-width of the carbon-13 resonance from the three magnetically equivalent methyl groups of the *tert*-butyl substituent of ester **1b** measures 2.3 Hz, which compares to line widths of the remaining signals ( $2.2 \pm 0.8$  Hz). O-Cumyl esters of **1a** exert broad resonances for methyl carbons bound to C9 (for atom numbering, refer to Figures 4 and 6), due to hindered rotation of the tertiary alkyl group about the N,O-bond.<sup>[11,35]</sup> For pro-diastereotopic methyl protons in **1b**, the phenomenon of hindered rotation is not similarly observable. From comparable steric size of a *tert*-butyl and a cumyl group,<sup>[54,55]</sup> we expect similar rate retarding effects on N,O-rotation.

For characterizing *tert*-butyl esters **1b–3b** via proton NMR-spectroscopy, we used chemical shifts from the singlet of the 4-methyl substituent of the heterocycle ( $2.4 \pm 0.1$  ppm), the quartet of C5-H in **2b** (6.15 ppm), and the singlet for the nine magnetically equivalent protons of the *tert*-butyl group ( $1.56 \pm 0.09$  ppm) (all values for CDCl<sub>3</sub> and 20 °C).

(vii) *Assigning thiocarbonyl stretchings and nitrogen-oxygen vibrations in heterocyclic O-(tert-butyl) thiohydroxamates.* For identifying infrared absorptions from the thiohydroxamate entity, we calculated vibrational spectra for minimum conformations of heterocyclic O-(*tert*-butyl) thiohydroxamates **1b–3b** (sections 4.1–4.2 for **2b–3b** and ESI for **1b**) at the DFT-D3/B3LYP/TZVP-level of theory, which includes dispersion energies for predicting vibrational modes more reliable than methods used hereafter for other purposes.

The strongest infrared absorption of 3-(*tert*-butoxy)-4-methylthiazole-2(3*H*)thione (**2b**) in a solution of acetonitrile is positioned at  $1300\text{ cm}^{-1}$  and originates from largely uncoupled C,N-stretching vibration toward C2.

The thiocarbonyl stretching vibration in ester **2b** couples to vibrations from the heterocyclic core, and bonds formed with substituents, particularly the alkoxy and the 4-methyl group, but also the C5-H bond. Vibrational coupling gives rise to three weak in intensity bands located at  $982$ ,  $1012$  and  $1153\text{ cm}^{-1}$ , showing moderate to small contribution from thiocarbonyl stretching. These bands are located with similar relative intensity at  $964$ ,  $1022$  and  $1152\text{ cm}^{-1}$  in the computed, scaled (0.99) vibrational spectrum (Figure 3).

Elongation of the N,O-bond couples with thiocarbonyl stretching, C,H-bending and

ring deformation vibrations from the heterocyclic core, leading to weak infrared absorptions at 883, 1138, 1155, and 1191  $\text{cm}^{-1}$  in the experimental spectrum and at 887, 1152, 1170 and 1206  $\text{cm}^{-1}$  in the computed spectrum.

Carbon-nitrogen stretching vibrations of 5-aryl-substituted thiazolethiones **1b** and **3b** couple to bending, torsional, skeletal, and deformation modes, but remain located in the spectral region of  $1300 \pm 50 \text{ cm}^{-1}$ . Thiocarbonyl stretchings couple in both compounds more extensively, providing up to six diagnostic but low-in-intensity vibrations between 950 and 1350  $\text{cm}^{-1}$  (ESI).

To sum up, thiocarbonyl stretching<sup>[56–61]</sup> and N,O-elongation combine in 3-(alkoxy)-4-methylthiazole-2(3*H*)thiones to a set of weak in intensity skeletal vibrations, spectroscopically located in the fingerprint-region.

**Figure 3** Experimental infrared spectrum of 3-(*tert*-butoxy)-4-methylthiazolethione **2b** (top; 20 °C in  $\text{CH}_3\text{CN}$ ) and computed harmonic frequencies for the equilibrium structure of **2b** (bottom; ● = contribution from C=S-stretching vibration; ○ contribution from N,O-stretching vibration; experimental = FTIR in acetonitrile, 75  $\mu\text{m}$  pathlength, 28 mM solution of **2b**; calculated = DFT-D3/B3LYP/TZVP, scaling factor 0.99; simulated = Lorentzian functions with a full width at half maximum of 15  $\text{cm}^{-1}$ ; for minimum structure of compound **2b** used in vibrational analysis, see Figure 6).

(viii) *Crystallography.* *p*-Nitrophenyl-substituted *tert*-butyl ester **3b** (MNPTTOtBu) crystallizes from a solution of diethyl ether and pentane in monoclinic space group  $P2_1/n$ . The unit cell comprises four molecules of MNPTTOtBu (**3b**), forming sulfur-sulfur [ $S1 \cdots S1' = 3.506(4)$  Å] and sulfur-hydrogen bonded ( $P/P$ ) $\cdots$ ( $M/M$ )-atropisomers [ $S7 \cdots H', C' = 2.975(4)$  Å]. Stereogenic elements in ester **3b** are the N,O-bond,<sup>[62]</sup> and the C,C-bond connecting the thiazolethione nucleus to the twisted *p*-nitrophenyl group [ $\pm 26.10(7)^\circ$ ] (Figure 4).

Bond angle  $N3, O8, C9 = 116.8(1)^\circ$  is larger than the standard bond angle at oxygen.<sup>[63]</sup> For primary, secondary, and tertiary *O*-alkyl derivatives of MAnTTOH (**1a**), the size of the  $N3, O8, C9$ -angle linearly correlates with the Taft-Dubois-steric substituent parameter, pointing to strain as major inductor for angle widening at O8.

**Figure 4** Ellipsoid graphic of 3-(*tert*-butoxy)-4-methyl-5-(4-nitrophenyl)thiazole-2(3*H*)thione (**3b**) in the solid state (50% probability level; 160 K; hydrogen atoms are drawn as circles of an arbitrary radius; oxygen is depicted in red, nitrogen in blue, and sulfur in orange).

Probably an electronic and not a steric effect is responsible for dispersion of bond angles at *tert*-butyl carbon C9, which gradually decrease from synperiplanar arranged methyl carbon C10 [ $111.6(1)^\circ$ ] via anticline carbon C12 [ $105.8(1)^\circ$ ] to the second anticline carbon C11 [ $103.1(1)^\circ$ ]. Similar bond angle dispersion is known from structural peroxide chemistry, and explained by  $\pi$ -bonding between the  $\sigma(O,O)$ -bond and the  $\sigma^*(C,C)$ -orbital in antiperiplanar or anticline orientation.  $\pi$ -Bonding reduces the size of involved bond angles (Figure 5).<sup>[64,65]</sup>

Lengths of single and double bonds of the thiazole-2(3*H*)thione core converge, pointing to electron delocalization similar to bonding in heteroaromatics (Table 2, entry 12).<sup>[11,35]</sup>

**Figure 5** Molecular orbital model on angle dispersion in *tert*-butyl thiohydroxamate **3b** (for similar interaction with  $\sigma^*(\text{C9},\text{C11})$ , refer to the text; O,C9,C11 = 103.1°; NP = 4-nitrophenyl; subscripts describe the confidence range of the final digit).

### 3 Formation and rearrangement of 1-(*tert*-butoxy)pyridine-2(1*H*)thione

(i) *Products of 1-hydroxypyridine-2(1H)thione-alkylation.* 1-Hydroxypyridine-2(1*H*)-thione (**4a**) provides 1-(*tert*-butoxy)pyridinethione **4b** in up 27% yield besides 15% *S*-(*tert*-butyl) thiohydroximate **9b**,<sup>[32,66]</sup> when treated with *O*-(*tert*-butyl)-*N,N*-diisopropyl isourea as specified in section 2 (Scheme 5).

In earlier studies, we had prepared *tert*-butyl ester **4b** from 2,2-dimethyl-2-bromopropane and 1-hydroxypyridine-2(1*H*)thione tetraethylammonium salt in a solution of dimethylformamide. Yields under such conditions never exceeded 1–4%.<sup>[32,66]</sup> When stored in a refrigerator the compound decomposed into yet unidentified pyridine derivatives.

**Scheme 5** Products of 1-hydroxypyridine-2(1*H*)thione-alkylation (<sup>a</sup> 2 experiments; <sup>b</sup> isolated from one representative experiment).

(ii) *The O-alkyl thiohydroxamate-O-alkyl sulfenate rearrangement.* A sample of 1-(*tert*-butoxy)pyridine-2(1*H*)thione (**4b**) purified by chromatography on silica gel furnished a yellow oil, displaying proton and carbon-13 NMR-chemical shifts a new compound. By comparing the data to references from our spectra library, we assigned molecular formula **10b** to the new product (Scheme 6).<sup>[67]</sup> On standing in a solution of deuteriochloroform, *O*-(*tert*-butyl) sulfenate **10b** decomposes into yet unidentified pyridine derivatives.

**Scheme 6** Rearrangement of 1-(*tert*-butoxy)pyridine-2(1*H*)thione (**4b**) [numbers in italics refer to carbon-13 NMR-shifts, figures in parenthesis to proton NMR-shifts ( $\text{CDCl}_3$ , 20 °C)].

(iii) *Synthesis of an O-alkyl pyridine-2-sulfenate as chemical reference.* The compound used as structural reference for characterizing rearranged product **10b** is *O*-pentyl pyridine-2-sulfenate **10c**, prepared in 51% yield from 1-(pentoxy)pyridine-2(1*H*)thione (**4c**) in photochemical reaction (Scheme 7 and the ESI). Sulfenate **10c** is a colorless oil, decomposing with moderate rate when contacted to silica gel during chromatography. Once pure, the compound is stable on storing in a refrigerator.

**Scheme 7** Products from anaerobic photodecomposition of 1-(pentoxy)pyridine-2(1*H*)thione (**4c**) [numbers in italics refer to carbon-13 NMR-shifts ( $\text{CDCl}_3$ , 20 °C)].

## 4 Structure, bonding, and stability of heterocyclic *O*-alkyl thiohydroxamates

### 4.1 Objective, models and validation of the approach

(i) *Outline.* To understand electronic interplay between *N*-heterocyclic thiolactames and alkoxy substitution at nitrogen, we investigated structure and bonding of heterocyclic *O*-alkyl thiohydroxamates using electronic structure methods.<sup>[68]</sup> For separating steric from electronic effects, we complemented structure/energy-data from *tert*-butyl esters by data for methyl substitution.

Before computationally investigating compounds, we assessed methods for

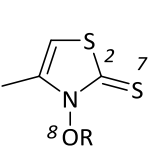

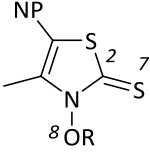

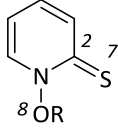

reproducing solid state structural properties of 3-(alkoxy)thiazole-2(3*H*)thiones and 1-(alkoxy)pyridine-2(1*H*)thiones (section 4.1). The finest method served as default for investigating conformational characteristics of heterocyclic *O*-alkyl thiohydroxamates (section 4.2), stability of isomers occurring in synthesis (section 4.3), N,O-bonding (section 4.4), and the phenomenon of steric stabilization (section 4.5).

(ii) *Theory*. For theoretically analyzing points of interest, we selected a double  $\zeta$ -basis set, abbreviated in the Gaussian03-systematic as 6-31+G\*\*.<sup>[69–71]</sup> The 6-31G\*\*-basis is parameterized for computing energy functions involving first, second, and third row atoms.<sup>[72,73]</sup> Polarization and diffuse functions<sup>[74]</sup> allow to treat with reasonable precision bonding between heteroatoms interacting by non-bonding electron pair effects, and bonding in cross-conjugated  $\pi$ -electron systems.<sup>[75]</sup>

All methods preselected for being combined with the 6-31+G\*\*-basis cover electron correlation: Becke's 3 parameter Lee-Yang-Parr hybrid functional (B3LYP),<sup>[76,77]</sup> Becke's half and half Lee-Yang-Parr hybrid functional (BHandHLYP),<sup>[78]</sup> and second order Møller-Plesset-perturbation theory (MP2)<sup>[79–81]</sup>. For translating results from density functional theory to a more tutorial bonding model, we used natural bond orbital (NBO)-theory.<sup>[82,83]</sup>

(iii) *Quality of the approach*. B3LYP-theory in combination with the 6-31+G\*\*-basis set reproduces structure of the thiohydroxamate group in 3-(*tert*-butoxy)-4-methylthiazole-2(3*H*)thione (**2b**) with deviation of 0.4% for the thiocarbonyl group, 0.4% for the nitrogen-oxygen bond, 1.3% for the nitrogen-carbon C2-bond, and 0.1% for the carbon-oxygen bond, when referenced toward the crystal structure of *O*-cumyl ester **2e** (Table 2, entries 1 and 11).<sup>[84]</sup> Bond angles at endocyclic nitrogen N3 and thiohydroxamate oxygen O8, and the dihedral angle along the N,O-bond, deviate no more than 1.4% from the experimental reference. Computed angles at *tert*-butyl carbon C9 gradually increase from 104.7 degrees for O8,C9,C11 via 105.2 degrees for O8,C9,C12 to 112.1 degrees for O8,C9,C10, reproducing the angle dispersion noted from the crystal structure of *tert*-butyl ester **3b** (Figures 4 and 5).

**Table 2** Computed and experimental parameters of *O*-alkyl thiohydroxamates

<sup>a</sup> B3LYP/6-31+G\*\*. <sup>b</sup> BHandHLYP/6-31+G\*\*. <sup>c</sup> MP2/6-31+G\*\*. <sup>d</sup> X-ray diffraction at 293 K. <sup>e</sup> Subscripts refer to the confidence range of the final digit. X-ray diffraction at 160 K. <sup>f</sup> X-ray diffraction at 297 K; Cx\* = *trans*-(1-*tert*-butyl)cyclohex-4-yl.

BHandHLYP-theory underestimates the length of the thiocarbonyl group, the N,O-distance, and the length between *tert*-butyl carbon C9 and thiohydroxamate oxygen O8. The method, however treats the thiohydroxamate C,N-bond more precisely than the B3LYP-density functional and MP2-theory (Table 2, entries 2, 6, and 8). Møller-Plesset-theory predicts a shorter distance between thiocarbonyl carbon and sulfur, a shorter bond between thiohydroxamate oxygen O8 and ester carbon C9, and a smaller bond angle at O8 (Table 2, entries 3 and 9).

From the quality of computed data, we chose B3LYP-theory as standard for

computing structure and bonding of *O*-alkyl thiohydroxamates. Our decision was guided by the ability of B3LYP-theory to reproduce the combination of N,O- and C=S-bond lengths. The lengths of the two bonds are interrelated by a mechanism explaining most questions raised with the study. For cross-checking thermochemical data we applied MP2-theory.

## 4.2 Heterocyclic *O*-alkyl thiohydroxamates

(i) *Conformation along the N,O-bond – the thiohydroxamate dihedral angle  $\omega$* . In the computed minimum conformer of MTTOTBu (**2b**), the *tert*-butyl substituent is offset by 91.3 degrees from the thiazolethione plane (Figure 6, Table 2, entry 1). Substituting methyl for *tert*-butyl reduces thiohydroxamate dihedral angle  $\omega = \text{C2,N,O,C}$  by 8 degrees. Replacing 4-methyl-2-thiooxo-(3*H*)thiaz-3-yl by 2-thiooxo-(1*H*)pyrid-1-yl increases  $\omega$  by 9 degrees for *O*-methyl- and for *O*-(*tert*-butyl) substitution. From this information we concluded that the preferred value of  $\omega$  is 90 degrees, allowing  $\pm 10$  degrees variation for responding to steric demand of the *O*-alkyl substituent and structural peculiarities of the heterocyclic core.

**Figure 6** Representative minimum conformers of heterocyclic *O*-alkyl thiohydroxamates (sulfur is depicted in yellow, oxygen in red, nitrogen in blue, carbon in gray, and hydrogen in white; B3LYP/6-31+G\*\*).

(ii) *Barrier to N,O-rotation*. Rotations about N,O-bonds in thiazole- and pyridine-derived thiohydroxamates occur in secondary and tertiary alkyl esters sufficiently slow, for being investigated by dynamic NMR-spectroscopy.<sup>[11,35,85,86]</sup> Simulating the process is feasible by a sequence of conformers differing in dihedral angle  $\omega$ , for covering a conformational space of 360 degrees. Given a plane of symmetry, rotating by 180 degrees provides a complete conformational analysis for rotation about the N,O-bond in thiazole- and pyridine-derived *O*-alkyl thiohydroxamates (Figure 7).

Displacing the *tert*-butyl substituent in ester **2b** from the equilibrium dihedral angle of 91.3 degrees by enlarging or reducing  $\omega$ , raises conformational energy until maxima are reached, showing synperiplanar orientation of carbons C9 and C2 ( $\omega = 0^\circ$ ) or antiperiplanar ( $\omega = 180^\circ$ ) (Figure 7). Assuming that likewise modelled high in energy conformers are maxima on the potential energy surface, Gibbs free energies differences between an equilibrium structure and planar a conformation translate into barriers to N,O-rotation (Table 3).

The modelled potential energy curve for N,O-rotation in *tert*-butyl ester **2b** is dissymmetric, showing a barrier of 49.7 kJ mol<sup>-1</sup> for torsional movement past the thione sulfur and 89.7 for the movement past the 4-methyl substituent (Figure 7). The dihedral angle/energy-profile for methyl ester **2d** is similar. Lower barriers correlate with smaller steric congestion at oxygen in *O*-methyl ester **2d** (Table 3, entries 1–2).

The experimental barrier to N,O-rotation in *O*-isopropyl thiohydroxamate **2f**, measured in a solution of dimethyl ether at a temperature of 200 Kelvin, is 42±7 kJ mol<sup>-1</sup>.<sup>[85]</sup> Extrapolating this value by the Gibbs-Helmholtz-equation furnishes a  $\Delta\Delta G^\ddagger$  of 46±9 kJ mol<sup>-1</sup> for a temperature of 298.15 Kelvin. By comparing experimental to modelled activation parameters, we concluded that the experimental barrier refers to the torsional movement of the *O*-isopropyl group past thione sulfur.

Modelling potential energy curves for rotating the *O*-(*tert*-butyl) group or the *O*-methyl group past hydrogen or past thione sulfur in pyridine-2(1*H*)thiones **4b** and **4d**, furnishes again dissymmetric dihedral angle/energy-curves (Figure 7). This time the barrier for shifting the alkyl substituent past thione sulfur is higher (63.5 kJ mol<sup>-1</sup>), than topomerizing a carbon substituent past hydrogen from the C6,H-bond (44.4 kJ mol<sup>-1</sup>).

The extrapolated barrier  $\Delta\Delta G^\ddagger$  to N,O-rotation in 1-(isopropoxy)pyridine-2(1*H*)thione (**4f**) is 36±2 kJ mol<sup>-1</sup>, which is in between the barrier modelled for torsional movements of a *tert*-butyl (**4b**) and a methyl group (**4d**) past the C6,H-bond.<sup>[85]</sup>

The steric effect exerted by thione sulfur in the pyridinethiones is more pronounced than in thiazolethiones, due to smaller exocyclic bond angle N,C2,S7, for example, of 123.7 in **4b** (128.9° in **2b**). Downsizing the substituent at thiohydroxamate oxygen from *tert*-butyl to methyl lowers barriers, supporting the hypothesis that steric effects contribute to conformational energy of N,O-rotamers (Table 3, entries 4–5).

To sum up, lowest in energy conformers of thiazole- and pyridine-derived *O*-alkyl thiohydroxamates show orthogonal alignment between heterocyclic plane and substituent at oxygen.

**Figure 7** Energy changes for rotating *tert*-butyl and methyl groups about N,O bonds in heterocyclic *O*-alkyl thiohydroxamates (B3LYP/6-31+G\*\*).

### 4.3 O-Alkyl thiohydroxamate isomers

(i) *Significance and design of the study.* To understand how heterocyclic groups effect stability of O-alkyl thiohydroxamates, we modelled heats of formation of isomers, coexisting in solution or in neat compounds, when being stored.<sup>[87–89]</sup> Product classes considered in this part of the project are O-alkyl thiohydroxamates, S-alkyl thiohydroximates and O-alkyl sulfenates. Minimum structures for the latter two product classes were obtained from potential energy scans of dihedral angles on the B3LYP-level of theory. For validating computed thermochemical data, we additionally minimized all energy functions in MP2-theory.

(ii) *S-alkyl thiohydroximates.* Minimum structures of thiazole-derived S-alkyl thiohydroximates **7b/7d** show a vertical displacement of the carbon substituent from the heterocyclic plane, declining from 67.2 degrees for the N3,C2,S7,C9-angle in case of *tert*-butyl-substitution (for **7b**) to 58.2 degrees for methyl derivative **7d**. Energy-minimized structures of 2-(alkylsulfanyl)pyridine 1-oxides show *gauche* conformation for atoms N1,C2,S7,C9 in case of *tert*-butyl substitution at sulfur (63.3 ° in **9b**), and *antiperiplanar* for methyl substitution (Figure 8).

The *antiperiplanar* conformation is the only structural motif encountered so far in crystal structures of 2-alkylsulfanyl-1,3-thiazole 3-oxides and -pyridine 1-oxides.<sup>[15,87,90,91]</sup>

**Figure 8** Minimum structures of selected S-alkyl thiohydroximates (sulfur is depicted in yellow, oxygen in red, nitrogen in blue, carbon in gray, and hydrogen in white; B3LYP/6-31+G\*\*).

(iii) *O-Alkyl sulfenates*. Minimum structures of *O*-alkyl sulfenates **10** and **12** show rooftop-conformations, as evident from dihedral angles along the sulfur-oxygen bond of  $108 \pm 1$  degrees for *tert*-butyl derivatives **10b** and **12b**, and  $89 \pm 2$  degrees for *O*-methyl derivatives **10d** and **12d** (Figure 9).<sup>[64]</sup> Sulfur-oxygen bond lengths predicted by theory are 1.688 Ångströms for pyridines **10b** and **10d**, and 1.684 Ångströms for thiazole-derived *O*-esters **12b** and **12d**.

A reference from crystallography, *O*-[*trans*-(4-*tert*-butyl)cyclohexyl]-2,4-dinitrophenylsulfenate, shows 2.7% shorter sulfur-oxygen bond [1.642(1) Å], but a similar value for the C,O,S,C-dihedral angle [ $92.0(1)^\circ$ ], agreeing, in summary, reasonably with the computed data, for example, for thiazole-derived sulfenates **12b/d**.<sup>[92]</sup>

**Figure 9** Minimum conformers of heterocyclic *O*-(*tert*-butyl) sulfenates (sulfur is depicted in yellow, oxygen in red, nitrogen in blue, carbon in gray, and hydrogen in white; B3LYP/6-31+G\*\*).

(iv) *Stability of isomers*. According to theory, *O*-alkyl sulfenates **10** and **12** are the

most stable of the *O*-alkyl thiohydroxamate isomers, regardless of the underlying heterocycle and the steric size of the carbon substituent. In Møller-Plesset-theory, predicted driving forces are slightly but systematically more pronounced than in density functional theory. Second in stability are *S*-alkyl thiohydroximates **7** and **9**, except of *S*-(*tert*-butyl) thiohydroximate **7b**, which is in both theories thermochemically less stable than *O*-(*tert*-butyl) thiohydroxamate **2b** (Tables 4 and 5).

The only isomerization described experimentally for 3-(alkoxy)thiazole-2(3*H*)thiones is a methyl shift from oxygen to sulfur. The reaction seems to be restricted to the solid state and requires about four years for attaining a 84/16-ratio of rearranged/non-rearranged isomers.<sup>[87]</sup>

Primary and secondary 1-(benzyloxy)pyridine-2(1*H*)thiones quantitatively isomerize within hours into 2-(*S*-benzylsulfanyl)pyridine 1-oxides.<sup>[88,90]</sup> Tertiary 1-alkoxypyridine-2(1*H*)thione **4b** quantitatively isomerizes into sulfenate **10b**. The origin of the specificity for selecting one or the other pathway is not evident from our data. By looking at the chemistry of 1-(alkoxy)-2(1*H*)pyridones and 1-(acyloxy)pyridine-2(1*H*)-thiones we suggest that rearrangement **4** → **9** occurs via substitution,<sup>[93]</sup> and rearrangement **4** → **10** by a frontier molecular orbital-controlled sigmatropic shift.<sup>[94]</sup>

1-(Methoxy)pyridine-2(1*H*)thione **4d** escaped for years synthesis and characterization.<sup>[45]</sup> We finally separated trace-amounts of a yellow oil, showing UV/Vis-absorptions of the pyridine-2(1*H*)thione-chromophore, and proton- and carbon-13 NMR-resonances proving the existence of *O*-methyl thiohydroxamate **4d**.<sup>[66]</sup> Within hours of standing in an amber-colored flask, in the dark, and in a refrigerator, the material decomposed into a complex mixture of yet unidentified pyridines. On the basis of information from the present study we believe that the compound rearranges into *O*-methyl sulfenate **10d** for undergoing secondary transformations.

Modelled thermochemical data, in summary, pose a useful guideline for organizing experimentally observed chemical differences between pyridine- and 1,3-thiazole-derived heterocyclic *O*-alkyl thiohydroxamates.

#### 4.4 $\pi$ -Bonding between nitrogen and oxygen

(i) *Bond order (BO)-analysis*. Bond orders are guidelines for rating bond strengths between a set of atoms.<sup>[95,96]</sup> Correlating experimental N,O-distances to bond orders from hydroxylamine ( $\text{BO}_{\text{N,O}} = 1$ ),<sup>[97]</sup> the triplet-nitrosyl anion (2), nitrogen monoxide (2.5), and the nitrosyl cation (3)<sup>[98,99]</sup> provides a linear relationship [ $d_{\text{N,O}}^{\text{exp}} = 1.6490 - 0.1966 \times \text{BO}_{\text{N,O}}$  (correlation coefficient  $R^2 = 0.9996$ ). A distance/bond order correlation for the same molecules, supplemented by N,O-distances from *O*-(*tert*-butyl) hydroxylamine ( $\text{BO}_{\text{N,O}} = 1$ ) and 2-nitroso-2-methylpropane (2) furnishes nearly identical gradient and intercept for a linear correlation [ $d_{\text{N,O}}^{\text{calc}} = 1.6316 - 0.1897 \times \text{BO}_{\text{N,O}}$  ( $R^2 = 0.9900$ ); B3LYP/6-31+G\*\*; ESI]. A third approach using harmonic force constants from vibrational spectroscopy for characterizing N,O-bond strengths<sup>[95,100,101]</sup> was not further pursued, once the degree of vibrational coupling in heterocyclic *O*-(*tert*-butyl) thiohydroxamates became apparent (cf. section 2).

The N,O-distance of 1.378 Å, determined by X-ray diffraction for *O*-(*tert*-butyl) thiohydroxamate **3b**, translates by the experimental correlation into a bond order of 1.38 (Table 6, entry 3). Theoretical bond order analysis provides value of 1.36. Computed N,O-distances of *O*-alkyl thiohydroxamates **2** and **4** correlates to bond orders of 1.35 for 3-(*tert*-butoxy)thiazolethione **2b**, 1.33 for methyl ester **2d** and *tert*-butyl ester **4b**, and 1.29 for (methoxy)pyridinethione **4d** (Table 6, entries 1–2 and 4–5).

**Table 6** N,O-Bond orders in heterocyclic *O*-alkyl thiohydroxamates

entry	compd / R	$d_{\text{N,O}} / \text{\AA}^a$	$\text{BO}_{\text{N,O}}^b$
1	<b>2b</b> / <i>t</i> Bu	1.3754	1.35
2	<b>2d</b> / CH <sub>3</sub>	1.3803	1.32
3	<b>3b</b> / <i>t</i> Bu	1.3734 (1.378) <sup>c</sup>	1.36 (1.38) <sup>d</sup>
4	<b>4b</b> / <i>t</i> Bu	1.3800	1.33
5	<b>4d</b> / CH <sub>3</sub>	1.3871	1.29

<sup>a</sup> Calculated (B3LYP/6-31+G\*\*). <sup>b</sup> Form  $d_{\text{N,O}}^{\text{calc}} = 1.6316 - 0.1897 \times \text{BO}_{\text{N,O}}$  (refer to the text). <sup>c</sup> Figure in parentheses refers to the experimental value (X-ray diffraction, 160 K). <sup>d</sup> From  $d_{\text{N,O}}^{\text{exp}} = 1.6490 - 0.1966 \times \text{BO}_{\text{N,O}}$  (refer to the text).

Bond order analysis for heterocyclic *O*-alkyl thiohydroxamates, in summary, points to partial double bonding between nitrogen and oxygen, becoming more significant as the steric size of the ester substituent increases, and being stronger in thiazole-derived thiohydroxamates than in pyridine derivatives.

(ii) *Molecular orbital model.* According to natural bond orbital (NBO)-theory,<sup>[82]</sup> bonding between nitrogen and oxygen in heterocyclic *O*-alkyl thiohydroxamates occurs by superimposing three  $\pi(\text{N,O})$ -bonds of different strength, to a  $\sigma(\text{N,O})$ -bond formed from the two heteroatoms with similar molecular orbital coefficients (Figure 10; ESI).

The first  $\pi$ -bond [ $\pi^1(\text{N,O})$ ] results from overlapping non-bonding electron pairs at oxygen and  $\sigma^*(\text{N,C})$ -orbitals from the heterocyclic core (Figure 10). In NBO-theory, the two non-bonding electron pairs at thiohydroxamate oxygen differ in hybridization, similar to ether oxygens.<sup>[102]</sup> One non-bonding electron pair shows 99.9% *p*-character, the second is *sp*-hybridized. In the minimum conformation, overlapping between the *p*-type orbital and the  $\sigma^*(\text{N,C})$ -orbitals is for stereoelectronic reason at maximum, contributing stronger to the  $\pi^1(\text{N,O})$ -bond, than the second interaction using the *sp*-hybridized non-bonding electron pair as donor.

The second  $\pi$ -bond,  $\pi^2(\text{N,O})$ , forms between the non-bonding electron pair at nitrogen and the  $\sigma^*(\text{O,C9})$ -orbital. NBO-theory predicts 99.9% *p*-character for the non-bonding electron pair at nitrogen, being incorporated into a planar heterocyclic core, and interacting with adjacent  $\pi$ -systems, particularly the thiocarbonyl group.

$\sigma$ -Electrons from the heterocyclic core and the *O*-alkyl group overlap with the  $\sigma^*(\text{N,O})$ -orbital, to form a third  $\pi$ -bond,  $\pi^3(\text{N,O})$ . Populating the  $\sigma^*(\text{N,O})$ -orbital counterbalances to some extent bond order-increasing contributions from  $\pi^1(\text{N,O})$ - and  $\pi^2(\text{N,O})$ -bonding.

By relative bond energy, the  $\pi^1(\text{N,O})$ -bond in thiazolethiones **2b** and **2d** ( $55 \pm 2 \text{ kJ mol}^{-1}$ ) is stronger than in pyridinethiones **4b** and **4d** ( $45 \pm 3 \text{ kJ mol}^{-1}$ ). The strength of the  $\pi^2(\text{N,O})$ -bond depends on alkyl substitution at ester oxygen, gradually rising from methyl esters **2d** and **4d** ( $11 \text{ kJ mol}^{-1}$ ) via *tert*-butyl ester **4d** ( $17 \text{ kJ mol}^{-1}$ ) to 3-(*tert*-butoxy)thiazolethione **2d** ( $76 \text{ kJ mol}^{-1}$ ). Strength of  $\pi^3(\text{N,O})$ -bonding, again, depends on the nature of the heterocyclic core and is higher for thiazolethiones **2b** and **2d** ( $70 \pm 1 \text{ kJ mol}^{-1}$ ) than for pyridinethiones **4b** and **4d** ( $54 \pm 1 \text{ kJ mol}^{-1}$ ) (ESI).

Molecular orbital theory, in summary, relates higher N,O-bond orders in thiazole-derived *O*-alkyl thiohydroxamates to stronger  $\pi(\text{N,O})$ -bonds.

**Figure 10** Molecular orbital model for  $\pi$ -bonding between nitrogen and oxygen in thiazole-derived *O*-alkyl thiohydroxamates (NBO-analysis; X = C or H; ESI).

(iii) *Dihedral angle dependency of  $\pi(\text{N,O})$ -bond strength.* Bond strengths of  $\pi^1(\text{N,O})$ - and  $\pi^2(\text{N,O})$ -bonds depend on the size of dihedral angle  $\omega$ . Strength of the bond  $\pi^3(\text{N,O})$  is nearly independent from  $\omega$ . Energies of bonds  $\pi^1(\text{N,O})$  and  $\pi^2(\text{N,O})$  reach maxima at  $\omega = 90$  degrees, and minima for 0 and 180 degrees. Increasing or decreasing  $\omega$ , starting from 90-degrees, reduces  $\pi(\text{N,O})$ -bond strengths and causes the distance between nitrogen and oxygen to increase. The distance between carbon C2 and sulfur S7 from the thiocarbonyl group shortens upon rotating the alkyl group toward methyl in **2** and hydrogen in **4**, and lengthens for alkyl group rotation toward thione sulfur. Bond distances between nitrogen and carbon C2 follow this trend, however, with opposite sign (Figure 11).

In crystal structures, the *O*-alkyl substituent is offset by  $90 \pm 10$  degrees from the thiohydroxamate plane.<sup>[35,87]</sup> Orthogonal arrangement takes profit from maximum  $\pi(\text{N,O})$ -bond energy. From this information we concluded that a fraction of the barrier to N,O-rotation is stereoelectronic in origin. The remaining fraction should be steric of origin, since energies of non-bonding electron pairs at nitrogen and oxygen vary insignificantly upon N,O-rotation, and not with the systematic expected for a conformational effect of Coulomb repulsion.<sup>[103–105]</sup> We therefore concluded that non-bonding electron pair repulsion plays a secondary role, if any, for explaining barriers to N,O-rotation in heterocyclic *O*-alkyl thiohydroxamates (ESI).<sup>[85]</sup>

**Figure 11** Dihedral angle dependency of thiohydroxamate bond lengths, exemplified by torsional movement of the *tert*-butyl group in 3-(*tert*-butoxy)thiazolethione **2b** (for indexing of atom positions, see Figure 6).

#### 4.5 Responses to thiohydroxamate bond angle variation

(i) *Response from steric encroachment.* The size of bond angle N,O,C9 experimentally correlates with steric encroachment exerted by alkyl substitution at thiohydroxamate oxygen.<sup>[35]</sup> Density functional theory reproduces this trend, predicting 6.4 degrees larger N,O,C9-angle by substituting *tert*-butyl for methyl in 3-(alkoxy)-4-methylthiazole-2(3*H*)thiones (Table 2, entries 1 and 4) and 5.5 degrees for the same substitution in 1-(alkoxy)pyridine-2(1*H*)thiones (Table 2, entries 7 and 10).

(ii) *Response from hybridization at oxygen.* Increasing the N,O,C9-angle size from 90 to 130 degrees changes hybridization at oxygen. NBO-theory predicts the *p*-character of the more stabilized non-bonding electron pair to increase by this variation, beginning at 32% for a N,O,C9-bond angle of 90 degrees, via 48% for the equilibrium structure (118.1 °) to 55% for 130 degrees (values for **2b**; for data of **2c**, **4b**, and **2d**, refer to the ESI). The second non-bonding electron pair at oxygen retains full *p*-character. The percentage of *p*-character of non-bonding electron pairs at oxygen correlates with orbital energy, and the ability to donate electrons in  $\pi$ (N,O)-interactions. Stronger  $\pi$ (N,O)-bonds show up in shorter N,O-bonds (Figures 12 and 13). Steric congestion at thiohydroxamate oxygen, in summary, strengthens the N,O-bond.

**Figure 12** Bond angle dependency of  $\pi(N,O)$ -bond energy in heterocyclic *O*-alkyl thiohydroxamates [ $E_{\pi(N,O)} = E_{\pi^1(N,O)} + E_{\pi^2(N,O)} + E_{\pi^3(N,O)}$ ; cf. Figure 10]

**Figure 13** Correlation between thiohydroxamate bond angle  $N,O,C9$  and  $N,O$ -bond lengths in heterocyclic *O*-alkyl thiohydroxamates.

(iii) *Response from the carbon-sulfur double bond.*  $\pi^1(N,O)$ -bonding transfers electron density from oxygen to nitrogen. Nitrogen is the donor for the  $\pi^2(N,O)$ -bond, but also for a stabilizing interaction with the  $\pi^*(C2,S7)$ -orbital from the thiocarbonyl group. The response to widening the  $N,O,C9$ -angle from the thiocarbonyl group is lengthening of the  $C2,S7$ -distance in combination with shortening of the  $N,O$ -bond (Figure 14).

(iv) *Response from crystallography.* Inverse  $N,O/C=S$ -correlations were discovered by crystallographers, stating that thiazole-derived *O*-alkyl thiohydroxamates respond to steric encroachment at oxygen by shortening and thus strengthening the  $N,O$ -bond. Lengthening

of C=S bonds was proposed to energetically counterbalance N,O-bond strengthening. From a smaller gradient of the N,O/C=S-correlation in the pyridine-2(1*H*)thione series, crystallographers concluded that this type of heterocycle is not similarly able to cope with steric congestion at thiohydroxamate oxygen.<sup>[35]</sup>

**Figure 14** Correlation between nitrogen-oxygen and thiocarbonyl bond lengths in heterocyclic *O*-alkyl thiohydroxamates

## 5. *tert*-Butoxyl radicals from heterocyclic *O*-(*tert*-butyl) thiohydroxamates

### 5.1 Disconnecting ground state stabilizing effects

For liberating alkoxy radicals from 3-(alkoxy)thiazole-2(3*H*)thiones, the ground state stabilizing mechanism has to be disconnected, for example, by changing the electronic state or chemically modifying the thiohydroxamate group. In this study, we used photoexcitation for liberating *tert*-butoxyl radicals, which were spin-trapped (section 5.2), or added to styrene (section 5.3).

### 5.2 Spin trapping of *tert*-butoxyl radicals

When photoexcited with 350 nm-light in solutions of benzene, *O*-*tert*-butyl thiohydroxamates **1b–3b** react with 5,5-dimethylpyrroline 1-oxide (DMPO) to provide nitroxyl radical **13**, as shown by a diagnostic electron spin resonance (ESR) at a *g*-factor of 2.009. The hyperfine structure of the resonance shows  $\alpha$ -coupling from nitrogen-14,  $\beta$ - and  $\gamma$ -couplings from protons.<sup>[39,106,107]</sup> (Table 7 and Figure 15).

**Table 7** ESR-spectroscopic data of pyrrolidine 1-oxyl radical **13** obtained from photoreactions between *O*-(*tert*-butyl) thiohydroxamates and DMPO

entry	<b>1b-3b</b> / R	<b>13</b>			
		<i>g</i>	<i>a<sub>N</sub></i> / G	<i>a<sub>H(β)</sub></i> / G	<i>a<sub>H(γ)</sub></i> / G
1	<b>1b</b> / <i>p</i> -C <sub>6</sub> H <sub>4</sub> (OCH <sub>3</sub> )	2.009	13.15	7.94	— <sup>b</sup>
2	<b>2b</b> / H	2.009	13.17	7.96	1.93
3	<b>3b</b> / <i>p</i> -C <sub>6</sub> H <sub>4</sub> (NO <sub>2</sub> )	2.009	13.17	7.94	1.90

**Figure 15** ESR-spectrum of nitroxyl radical **13**, obtained from photoreaction of MNPTTOtBu (**3b**) and DMPO in a solution of benzene at room temperature.

### 5.3 Trapping of *tert*-butoxyl radicals by intermolecular addition

Photolyzing a solution of 3-(*tert*-butoxy)thiazoethione **2b** in benzene, being 2.76 molar in styrene and 0.13 molar in bromotrichloromethane, furnishes 2-bromo-2-phenyl-1-(*tert*-butoxy)ethane (**14**) in 26% yield (Scheme 8).

A proton NMR-spectrum of bromohydrin ether **14** recorded in deuterochloroform displays a diagnostic singlet at 1.17 ppm for the three magnetically equivalent methyl groups of the *tert*-butyl group. Diastereotopic protons at carbon C1 furnish baseline separated signals at 3.81 and 3.91 ppm, being split by hyperfine couplings into doublet of doublets.

**Scheme 8** Multicomponent reaction for synthesis of 2-bromohydrin ether **14**.

Bromohydrin ether **14** forms by adding *tert*-butoxyl radical **1b** to the terminal alkene carbon of styrene, which is the position bearing in the highest occupied molecular orbital and the lowest unoccupied molecular orbital the largest molecular orbital coefficient (Scheme 9).<sup>[12,108,109]</sup> Trapping of adduct **III** by bromotrichloromethane furnishes bromohydrin ether **14** in yields comparing to the *tert*-butoxyl radical addition product to norbornene.<sup>[110]</sup> The trichloromethyl radical, which is left from homolytic displacement at bromotrichloromethane, has three major options for stabilizing secondary reactions. The first option is to add to the thiocarbonyl sulfur of 3-(*tert*-butoxy)thiazole-2(3*H*)thione **2b**, yielding 2-(trichloromethylsulfanyl)thiazole **15**. The second option is to add to the alkenyl group of styrene, giving rise to 3,3,3-trichloro-1-bromo-1-phenylpropane (**16**).<sup>[111]</sup> The third option is to combine with a second of its kind to give hexachloroethane (**17**). Hexachloroethane (**17**) and products of bromotrichloromethane addition across an alkene  $\pi$ -bond are common contaminants in bromohydrin ether syntheses by the alkoxyl radical method. For unknown reasons, we did not isolate expected trapping product **15** (Figure 16).

**Scheme 9** Addition-substitution sequence for explaining formation of bromohydrin ether **14**.

**Figure 16** Expected (**15**) and detected (**16** and **17**) products formed from trichloromethyl radical reactions.

### Concluding Remarks

Thiazole-derived *O*-(*tert*-butyl) thiohydroxamates are stable compounds, liberating *tert*-butoxyl radicals by homolytically breaking the N,O-bond when activated with light or attacked by radicals at thione sulfur. The esters are accessible in up to 64% yield from thiohydroxamic acids and an *O*-(*tert*-butyl) isourea. Characterizing products of thiohydroxamate *O*-alkylation is feasible from diagnostic thiocarbonyl carbon-13 resonances and stretching vibrations associated with the 3-alkoxy-4-methylthiazole-2(3*H*)thione core.

Ground state stability of heterocyclic *O*-(*tert*-butyl) thiohydroxamates arises from partial multiple bonding between nitrogen and oxygen, being explained in molecular orbital by a  $\sigma$ (N,O)-bond and three superimposed  $\pi$ (N,O)-bonds of different strengths. Steric congestion at thiohydroxamate oxygen strengthens  $\pi$ (N,O)-bonding, explaining the unusual stability of 3-(*tert*-butoxy)thiazole-2(3*H*)thiones. 1-(Alkoxy)pyridine-2(1*H*) thiones exert a similar stabilizing mechanism, however, being less effective.

The underlying principle, to use non-bonding electron pairs from proximate heteroatoms for strengthening a weak  $\sigma$ -bond by supplementary  $\pi$ -interactions, according to our interpretation, is not restricted to the N,O-bond of thiohydroxamates. Nitrogen, phosphorous, oxygen, sulfur, fluorine, chlorine, bromine, and iodine in all possible combinations are in principle able to form  $\sigma$ - and  $\pi$ -bonds according to the suggested model.

The attractive feature of the N,O-bonding model developed in this article is the fact that the heteroatom-heteroatom bond stabilizing mechanism applies to the ground state. On the leave of the ground state, stabilizing interactions disappear, making the heteroatom-heteroatom bond a predetermined breaking point for liberating reactive intermediates. Insights of this kind provide a guideline for designing new radical precursors and adapting their properties. For us, the approach provides perspectives for examining standing

questions on polar selectivity effects in tertiary alkoxy radical additions, which we pursue at the moment in our laboratory.

## Experimental

### 1. General

For general laboratory practice and instrumentation see the ESI.

### 2. 3-Hydroxy-4-methyl-5-(4-nitrophenyl)-thiazole-2(3H)thione (3a)

#### 2.1 1-Chloro-1-(4-nitrophenyl)propan-2-one

A solution of sulfur chloride (5.51 g, 3.3 mL, 40.8 mmol) in dichloromethane (15 mL) is added in a dropwise manner to an ice-cooled (0 °C) to a solution of 1-(4-nitrophenyl)-propan-2-one (**5**)<sup>[112]</sup> (6.00 g, 33.5 mmol) in dichloromethane (20 mL), causing a change in color from red to pale yellow. The reaction mixture was continued for two hours at 21 °C, and washed afterwards with an aqueous saturated solution of NaHCO<sub>3</sub> (50 mL) and water (50 mL). The organic phase was separated, dried (MgSO<sub>4</sub>), and concentrated under reduced pressure to leave an orange oil, which was purified by column chromatography using diethyl ether/pentane = 1:1 (v/v) as eluent. Yield: 5.47 g (25.6 mmol, 76 %), pale yellow oil, which crystallizes on standing at -32 °C. *R*<sub>f</sub> = 0.50 [diethyl ether/pentane = 1:1 (v/v)]. M.p. 38 °C. <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz) δ 2.31 (s, 3 H), 5.40 (s, 1 H), 7.60–7.64 (m, 2 H), 8.24–8.27 (m, 2 H). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 100.6 MHz) δ 26.1, 64.6, 124.1, 129.0, 141.7, 148.2, 199.1. MS (EI) *m/z* (%) 213 (M<sup>+</sup>, <1), 172 (35), 171 (100), 163 (5), 151 (13), 141 (22), 133 (7), 124 (20), 112 (12), 103 (8), 89 (70), 77 (18), 63 (42), 51 (14). Anal. Calcd. for C<sub>9</sub>H<sub>8</sub>NO<sub>3</sub>Cl (213.62): C, 50.60; H, 3.77; N, 6.56; Found: C, 50.24; H, 3.90; N, 6.52.

#### 2.2 1-(Ethoxythiocarbonylsulfanyl)-1-(4-nitrophenyl)propan-2-one

A solution of 1-chloro-1-(4-nitrophenyl)-propan-2-one (339 mg, 1.59 mmol) in acetone (2 mL) was added at 0 °C to a suspension of potassium *O*-ethyldithiocarbonate (256 mg, 1.60 mmol) in acetone (2 mL). The resulting slurry was stirred for two hours at 21 °C. Solids were filtered off, and the filtrate concentrated under reduced pressure. The remaining red oil was purified by chromatography using diethyl ether/pentane = 1:1 (v/v) as eluent. Yield: 359 mg (1.20 mmol, 75 %), pale yellow solid. *R*<sub>f</sub> = 0.57 [diethyl ether/pentane =

1:1 (v/v)]. m.p. 61 °C.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 600 MHz)  $\delta$  1.40 (t,  $J$  = 7.0 Hz, 3 H), 2.32 (s, 3 H), 4.61 (q,  $J$  = 7.1 Hz, 2 H), 5.76 (s, 1 H), 7.50–7.59 (m, 2 H), 8.18–8.25 (m, 2 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100.6 MHz)  $\delta$  13.7, 28.9, 63.7, 71.1, 124.1, 130.1, 140.9, 147.9, 200.2, 211.2. MS (EI)  $m/z$  (%) 299 ( $\text{M}^+$ , 3), 266 (100), 257 (24), 239 (57), 211 (68), 194 (23), 180 (32), 168 (64), 152 (60), 137 (27), 131 (35), 121 (76), 103 (41), 103 (8), 89 (80), 77 (77), 63 (61), 51 (34). Anal. Calcd. for  $\text{C}_{12}\text{H}_{13}\text{NO}_4\text{S}_2$  (299.36): C, 48.15; H, 4.38; N, 4.68; S, 21.42, Found: C, 48.36; H, 4.50; N, 4.74. S, 21.48.

## 2.2 1-(Ethoxythiocarbonylsulfanyl)-1-(4-nitrophenyl)propan-2-one oxime

Hydroxyl ammonium hydrochloride (94.3 mg, 1.36 mmol) and pyridine (104 mg, 1.31 mmol) were sequentially added in one portion at added 0 °C to a suspension of 1-(ethoxythiocarbonylsulfanyl)-1-(4-nitrophenyl)propan-2-one (315 mg, 1.05 mmol) in methanol (5 mL). The resulting mixture was stirred for fourteen hours at 22 °C and afterwards concentrated under reduced pressure. The remaining oil residue was taken up in dichloromethane (20 mL) and washed successively with 0.5 M aqueous hydrochloric acid (20 mL) and brine (20 mL). The organic phase was dried ( $\text{MgSO}_4$ ) and concentrated under reduced pressure. The remaining oil oil was purified by chromatography, using diethyl ether/pentane = 1:2 (v/v) as eluent. Yield: 260 mg (828 mmol, 79 %), pale yellow oil, 86/14-mixture of (*E*)/(*Z*)-stereoisomers (isomers A and B). Anal. Calcd. for  $\text{C}_{12}\text{H}_{14}\text{N}_2\text{O}_4\text{S}_2$  (314.37) (mixture of stereoisomers A and B): C, 45.85; H, 4.49; N, 8.91; S, 20.40, Found: C, 45.74; H, 4.55; N, 8.83, S, 20.37. *Isomer A*.  $R_f$  = 0.38 [diethyl ether/pentane = 1:2 (v/v)]  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 200 MHz)  $\delta$  1.38 (t,  $J$  = 7.1 Hz, 3 H), 1.93 (s, 3 H), 4.60 (q,  $J$  = 7.1 Hz, 2 H), 5.65 (s, 1 H), 7.53–7.66 (m, 2 H), 8.05 (br. s, 1 H), 8.15–8.26 (m, 2 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100.6 MHz)  $\delta$  13.66, 13.70, 57.7, 70.7, 123.7, 129.8, 144.4, 147.5, 155.2, 211.1. *Isomer B*.  $R_f$  = 0.26 [diethyl ether/pentane = 1:2 (v/v)].  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 200 MHz)  $\delta$  1.38 (t,  $J$  = 7.1 Hz, 3 H), 1.99 (s, 3 H), 4.63 (q,  $J$  = 7.1 Hz, 2 H), 6.51 (s, 1 H), 7.55–7.62 (m, 2 H), 8.16–8.23 (m, 2 H), 8.60 (br. s, 1 H, OH).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100.6 MHz)  $\delta$  13.6, 18.4, 49.8, 70.8, 123.9, 129.1, 143.2, 147.5, 153.2, 210.5.

## 2.4 3-Hydroxy-4-methyl-5-(4-nitrophenyl)thiazole-2(3*H*)thione (3a)

A solution of (ethoxythiocarbonylsulfanyl)-1-(4-nitrophenyl)propan-2-one oxime (5.58 g, 17.7 mmol) in dichloromethane (104 mL) was added at 0 °C to a solution of

potassium hydroxide [4.00 g, 86% (w/w), 61.3 mmol] in water (104 mL). The resulting suspension was stirred for two hours at 23 °C and hereafter diluted with water (~700 mL), all solids were dissolved. The aqueous layer was separated, washed with dichloromethane (200 mL) and acidified to pH 1 by adding concentrated hydrochloric acid. The precipitate was collected and dried. Yield: 4.42g (16.5 mmol, 93 %), yellow solid. The crude precipitate was used for preparing *O*-esters. An analytically pure sample was obtained by crystallizing from dimethyl formamide. Yellow needles. M.p. 162 °C.  $^1\text{H}$  NMR (DMSO- $d_6$ ), 400 MHz)  $\delta$  2.38 (s, 3 H), 7.72 (d,  $J$  = 8.8 Hz, 2 H), 8.29 (d,  $J$  = 8.8 Hz, 2 H), 12.51 (br.s, 1 H).  $^{13}\text{C}$  NMR (DMSO- $d_6$ ), 100.6 MHz)  $\delta$  12.8, 114.5, 124.3, 129.0, 136.8, 137.4, 146.6, 177.3. UV (methanol):  $\lambda_{\text{max}}$  (lg  $\epsilon/\text{m}^2\text{mol}^{-1}$ ) 377 nm (3.15), 313 (2.94), 263 (2.90), 205 (3.28). Anal. Calcd. for  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_3\text{S}_2$  (268.31): C, 44.77; H, 3.01; N, 10.44; S, 23.90, Found: C, 44.61; H, 3.08; N, 10.46, S, 23.98.

### 3 Alkylation of 3-hydroxy-4-methylthiazole-2(3H)thiones with in situ-generated *O*-(*tert*-butyl)-*N,N*-diisopropyl isourea

#### 3.1 General method

Copper(I)-chloride (2 mol%) was added at 22 °C to solution of *tert*-butanol (5.5 mmol) and diisopropyl carbodiimide (5.5 mmol). The reaction mixture was stirred for twenty-four hours at 22 °C and hereafter transferred into a syringe, for being added (20  $\mu\text{L}/\text{min}$ ) to a solution of a 3-hydroxythiazole-2(3H)thione (**1a–3a**) or 1-hydroxypyridine-2(1H)thione (**4a**) in dichloromethane (2 mL/mmol) at 23 °C. After complete addition, solids were immediately filtered off and washed with dichloromethane ( $3 \times 10$  mL). Filtrate and washings were combined to furnish a clear solution, which was concentrated under reduced pressure. The remaining oil was purified by column chromatography ( $\text{SiO}_2$ ) using an eluent gradient specified individually below.

#### 3.2 Alkylation of 3-hydroxy-4-methylthiazole-2(3H)thione (**2a**)

Reagents: 3-hydroxy-4-methylthiazol-2(3H)thione (**2a**) (1.48 g, 10 mmol), *tert*-butanol (3.72 g, 50.0 mmol), DIC (6.30 g, 50.0 mmol) and copper(I)-chloride (98 mg, 1.00 mmol). Eluent gradient used for chromatographic purification: ether/pentane = 1:1 (v/v)  $\rightarrow$  acetone. 3-(2-Methylprop-2-oxy)-4-methylthiazole-2(3H)thione (**2b**). Yield: 988 mg (4.86 mmol, 49 %) off-white solid. M.p. 56–57 °C,  $R_f$  = 0.36 [diethyl ether/pentane = 1:1 (v/v)].  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ,

400 MHz)  $\delta$  1.57 (s, 9 H), 2.26 (d,  $J$  = 1.2 Hz, 3 H), 6.15 (q,  $J$  = 1.2 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  15.2, 28.8, 91.8, 102.9, 139.8, 184.1. UV (methanol):  $\lambda_{\text{max}}$  ( $\lg \varepsilon/\text{m}^2\text{mol}^{-1}$ ) 319 nm (3.05), 211 (2.99). IR ( $\text{CCl}_4$ )  $\nu_{\text{max}}$  /  $\text{cm}^{-1}$  2981, 2933, 1306, 1191, 1155, 1138, 1012, 982, 883, 839, 816, 854, 816, 727. Anal. Calcd. for  $\text{C}_8\text{H}_{13}\text{NOS}_2$  (203.32): C, 47.26; H, 6.44; N, 6.89; S, 31.54, Found: C, 47.09; H, 6.30; N, 6.87, S, 31.45. 2-(2-Methylpropyl-2-sulfanyl)-4-methylthiazole *N*-oxide (**7b**). Yield: 491 mg (2.42 mmol, 24 %) off-white solid. M.p. 105 °C.  $R_f$  = 0.41 (acetone).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 600 MHz)  $\delta$  1.43 (s, 9 H), 2.36 (d,  $J$  = 0.9 Hz, 3 H), 7.12 (d,  $J$  = 0.9 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 150.9 MHz)  $\delta$  13.9, 31.3, 52.5, 114.6, 135.5, 146.4. MS (EI)  $m/z$  (%) 203 ( $\text{M}^+$ , <1), 187 (4), 147 (61), 131 (100), 86 (20), 71 (16), 57 (44). Anal. Calcd. for  $\text{C}_8\text{H}_{13}\text{NOS}_2$  (203.32): C, 47.26; H, 6.44; N, 6.89; S, 31.54, Found: C, 47.37; H, 6.23; N, 6.94, S, 31.37.

### 3.3 Alkylation of 3-hydroxy-4-methyl-5-(4-nitrophenyl)thiazole-2(3H)thione (3a)

Reagents: 3-hydroxy-4-methyl-5-(4-nitrophenyl)thiazole-2(3H)thione (**3a**) (1.34 g, 4.99 mmol), *tert*-butanol (2.04 g, 27.5 mmol), DIC (3.47 g, 27.5 mmol) and copper(I)-chloride (51 mg, 515  $\mu\text{mol}$ ). Eluent gradient used for chromatographic purification: ether/pentane = 1:1 (v/v)  $\rightarrow$  ethyl acetate. 3-(2-Methylprop-2-oxy)-4-methyl-5-(4-nitrophenyl)-thiazole-2(3H)thione (**3b**). Yield: 624 mg (1.92 mmol, 39 %), fluffy yellow crystals. M.p. 153 °C.  $R_f$  = 0.33 [diethyl ether/pentane = 1:1 (v/v)].  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.64 (s, 9 H), 2.42 (s, 3 H), 7.49–7.52 (m, 2 H), 8.28–8.31 (m, 2 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  14.7, 28.9, 92.6, 116.4, 124.4, 128.9, 137.1, 137.3, 147.2, 183.3. UV (methanol):  $\lambda_{\text{max}}$  ( $\lg \varepsilon/\text{m}^2\text{mol}^{-1}$ ) 377 nm (3.18), 324 (2.96), 265 (2.99), 205 (3.33). IR ( $\text{CCl}_4$ )  $\nu_{\text{max}}$  /  $\text{cm}^{-1}$  2981, 2933, 1523, 1350, 1327, 1271, 1171, 1132, 1110, 1030, 990, 943, 910, 854, 816, 754, 695, 613, 566. Anal. Calcd. for  $\text{C}_{14}\text{H}_{16}\text{N}_2\text{O}_3\text{S}_2$  (324.42): C, 51.83; H, 4.97; N, 8.64; S, 19.76, Found: C, 51.70; H, 4.94; N, 8.64, S, 19.84. 2-(2-Methylpropyl-2-sulfanyl)-4-methyl-5-(4-nitrophenyl)-thiazole *N*-oxide (**8b**). Yield: 271 mg (837  $\mu\text{mol}$ , 17 %), orange oil.  $R_f$  = 0.26 (ethyl acetate).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.51 (s, 9 H), 2.52 (s, 3 H), 7.63–7.65 (m, 2 H), 8.33–8.35 (m, 2 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100.6 MHz)  $\delta$  13.2, 31.4, 53.0, 124.5, 129.0, 129.3, 136.6, 137.0, 143.8, 148.0. MS (EI)  $m/z$  (%) 220 (100), 190 (21), 174 (5), 163 (3), 147 (29), 135 (7), 121 (6), 115 (6), 103 (22), 91 (7), 77 (15), 69 (14), 63 (9), 51 (6). Anal. Calcd. for  $\text{C}_{14}\text{H}_{16}\text{N}_2\text{O}_3\text{S}_2$  (324.42): C, 51.83; H, 4.97; N, 8.64; S, 19.76, Found: C, 51.48; H, 5.26; N, 8.68, S, 19.85.

## 4 Alkylation of 1-hydroxypyridine-2(1H)thione (4a)

### 4.1 Alkylation with *tert*-butyl bromide

Reagents: 1-hydroxypyridine-2(1H)thione tetraethylammonium salt (2.72 g, 10.6 mmol), *tert*-butyl bromide (1.45 g, 10.6 mmol) and dimethyl formamide (35 mL). Eluent used for chromatographic purification: *tert*-butyl methyl ether. 1-(2-Methylprop-2-oxy)pyridine-2(1H)thione (**4b**). Yield: 70 mg (382  $\mu$ mol, 4 %), pale yellow solid, m.p. 54 °C,  $R_f$  = 0.61 (*tert*-butyl methyl ether).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 600 MHz)  $\delta$  1.49 (s, 9 H), 6.52 (td,  $J_t$  = 6.9 Hz,  $J_d$  = 1.7 Hz, 1 H), 7.05 (ddd,  $J$  = 8.6, 6.9, 1.5 Hz, 1 H), 7.63 (dd  $J$  = 8.0, 1.5 Hz, 1 H), 7.66 (dd,  $J$  = 6.5, 1.7 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 150 MHz)  $\delta$  27.7, 90.7, 112.2, 132.0, 137.7, 139.9, 179.2. UV (ethanol):  $\lambda_{\text{max}}$  (lg  $\varepsilon/\text{m}^2\text{mol}^{-1}$ ) 364 nm (2.68), 291 (3.03). Anal. Calcd. for  $\text{C}_9\text{H}_{13}\text{NOS}$  (183.27): C, 58.98; H, 7.15; N, 7.64; S, 17.49, Found: C, 58.68; H, 6.97; N, 7.65, S, 17.09.

### 4.2 Alkylation with in situ-generated *O-tert*-butyl-*N,N*-diisopropyl isourea

Reagents: 1-hydroxypyridine-2(1H)thione (643 mg, 5.06 mmol), *tert*-butanol (2.04 g, 27.5 mmol), DIC (3.47 g, 27.5 mmol) and copper(I)-chloride (50.0 mg, 505  $\mu$ mol). Eluent gradient used for chromatographic purification: diethyl ether  $\rightarrow$  acetone. Yield: 221 mg (1.21 mmol, 24 %), yellow oil, 82/18-mixture of 1-(2-methylprop-2-oxy)pyridine-2(1H)thione (**4b**) and *O*-(2-methylprop-2-yl) pyridine-2-sulfenate (**10b**).  $R_f$  = 0.80 (diethyl ether). *O*-(2-methylprop-2-yl) pyridine-2-sulfenate (**10b**).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.35 (s, 9 H), 6.92 (ddd,  $J$  = 7.5, 4.8, 1.1 Hz, 1 H), 7.34 (dt,  $J_d$  = 8.1 Hz,  $J_t$  = 1.1 Hz, 1 H), 7.60 (td,  $J_t$  = 7.8 Hz,  $J_d$  = 1.9 Hz, 1 H), 8.32 (d,  $J$  = 4.8 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100.6 MHz)  $\delta$  27.6, 83.4, 117.1, 119.0, 136.4, 148.7, 167.1.  $^1\text{H}$  NMR ( $\text{C}_6\text{D}_6$ , 400 MHz)  $\delta$  1.13 (s, 9 H), 6.42 (ddd,  $J$  = 7.5, 4.8, 1.1 Hz, 1 H), 7.08 (td,  $J_t$  = 7.8 Hz,  $J_d$  = 1.9 Hz, 1 H), 7.25 (dt,  $J_d$  = 8.1 Hz,  $J_t$  = 1.1 Hz, 1 H), 8.21–8.27 (m, 1 H).  $^{13}\text{C}$  NMR ( $\text{C}_6\text{D}_6$ , 100.6 MHz)  $\delta$  27.5, 82.8, 116.9, 118.9, 136.2, 149.0, 167.8. 2-(2-methylpropyl-2-sulfanyl)pyridine 1-oxide (**9b**). Yield: 109 (594,  $\mu$ mol, 12 %), colorless oil.  $R_f$  = 0.31 (acetone).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.52 (s, 9 H), 7.08 (ddd,  $J$  = 1.9, 6.5, 6.6 Hz, 1 H), 7.6 (td,  $J_d$  = 1.4 Hz,  $J_t$  = 7.5 Hz, 1 H), 7.52 (dd,  $J$  = 8.0, 2.0 Hz, 1 H), 8.27 (dd,  $J$  = 1.1, 6.4 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 150.9 MHz)  $\delta$  30.9, 47.9, 122.4, 124.4, 129.0, 139.8, 149.7. GC/MS (EI)  $m/z$ . (%): 17.95 min/ 183 ( $\text{M}^+$ , <1), 167 (5), 127 (30), 111 (100), 78 (16), 67 (33), 57 (19). HRMS ( $\text{EI}^+$ )  $m/z$  183.0718 ( $\text{M}^+$ ); calculated mass for  $\text{C}_9\text{H}_{13}\text{NOS}$ :183.0718.

## 5 Spin trapping with 5,5-dimethyl-1-pyrroline 1-oxide (DMPO)

A solution of an *O*-alkyl thiohydroxamate [9.59 mg (31.0  $\mu\text{mol}$ ) for **1b**, 5.97 mg (29.4  $\mu\text{mol}$ ) for **2b**, 10.0 mg (30.8  $\mu\text{mol}$ ) for **3b**] in benzene (300  $\mu\text{L}$ , 0.10 M) was transferred into an ESR-tube, charged with a solution of 5,5-dimethyl-1-pyrroline 1-oxide (3.59 mg, 31.7  $\mu\text{mol}$ ) in benzene (300  $\mu\text{L}$ , 0.11 M). The solution was flushed for five minutes with a gentle stream of argon, photolyzed for two minutes at  $\sim 25^\circ\text{C}$  in a Rayonet<sup>®</sup> chamber reactor equipped with twelve 350 nm light bulbs, and placed into the cavity of an ESR-spectrometer. The spectral data from trapping experiments using *O*-(*tert*-butyl) esters **1b–3b** are summarized in Table 7.

## 6 Intermolecular trapping with styrene and bromotrichloromethane

A solution of 3-(*tert*-butoxy)thiazole-2(3*H*)thione **2b** (208 mg, 1.02 mmol), styrene (2.22 g, 21.3 mmol,  $c_0 = 2.76\text{ M}$ ), and bromotrichloromethane (1.00 mL, 10.0 mmol) in benzene (7.7 mL) was photolyzed at  $\sim 25^\circ\text{C}$  in a Rayonet<sup>®</sup> chamber reactor equipped with twelve 350 nm light bulbs, until the starting material was completely consumed ( $\sim 30\text{ min}$ , tlc). The solution was concentrated under reduced pressure to leave an oil, which was purified by chromatography ( $\text{SiO}_2$ ). Eluent used for chromatographic purification: ether/pentane = 1:50 (v/v)  $\rightarrow$  ether/pentane = 1:20 (v/v). 2-Brom-2-phenyl-1-(2-methyl-2-propoxy)ethane (**14**). Yield: 69.3 mg (270  $\mu\text{mol}$ , 26 %), colorless oil.  $R_f = 0.65$  [diethyl ether/pentane = 1:20 (v/v)].  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.20 (s, 9 H), 3.80 (dd,  $J = 6.4, 10.4\text{ Hz}$ , 1 H), 3.90 (dd,  $J = 7.3, 10.4\text{ Hz}$ , 1 H), 4.99 (t,  $J = 6.8\text{ Hz}$ , 1 H), 7.29–7.39 (m, 3 H), 7.41–7.46 (m, 2 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100.6 MHz)  $\delta$  27.5, 53.5, 67.0, 73.8, 127.9, 128.4, 128.5, 139.6. GC/MS (EI)  $m/z$  (%): 16.22 min/ 258 ( $\text{M}^+$ , <1), 185 (16), 183 (17), 147 (46), 120 (19), 104 (64), 103 (30), 91 (56), 78 (19), 77 (17), 65 (13), 57 (100). Anal. Calcd. for  $\text{C}_{12}\text{H}_{17}\text{OBr}$  (257.17): C, 56.05; H, 6.66; Found: C, 56.18; H, 6.60.

**Acknowledgements.** We thank Dr. Reinhard Philipp for recording EPR-spectra of compounds 13 and helpful technical suggestions. This work is part of the Ph.D. thesis of C.S.

A8	Computational Chemistry.....	214
A9	Crystallography.....	279
A10	References .....	280

**A1 General Remarks:** (i) Numbering of compounds in the *Electronic Supporting Information* and the accompanying publication are consistent. (ii) References refer exclusively to the *Electronic Supporting Information*.

## A2 Instrumentation

**A2.1 NMR-spectroscopy:** Proton- and carbon-13-NMR spectra were measured with FT-NMR DPX 200, DPX 400 and DMX 600 instruments (*Bruker*). Chemical shifts refer to the  $\delta$ -scale. Proton resonances of residual non-deuterated solvent molecules ( $\delta_{\text{H}}$  7.26 for  $\text{CDCl}_3$ ;  $\delta_{\text{H}}$  7.16 for benzene;  $\delta_{\text{H}}$  2.50 for DMSO), and carbon-13 chemical shifts of  $\text{CDCl}_3$  ( $\delta_{\text{C}}$  77.0),  $\text{C}_6\text{D}_6$  ( $\delta_{\text{C}}$  128.06), and  $\text{DMSO}-d_6$  ( $\delta_{\text{C}}$  39.52) served as internal standards.

**A2.2 Electron impact mass spectrometry:** Mass spectra (EI, 70 eV) were recorded with a Mass Selective Detector HP 6890 (*Hewlett Packard*).

**A2.3 High resolution mass spectrometry** were measured with a GCT Premier Micromass instrument (*Waters*).

**A2.4 Optical rotations** of chiral compounds at  $\lambda = 589 \text{ nm}$  were recorded with a Krüss P3001/RS-polarimeter and a Perkin-Elmer polarimeter type 241 ( $\lambda_1 = 546 \text{ nm}$  und  $\lambda_2 = 579 \text{ nm}$ ), and extrapolated using the Drude equation.<sup>[1]</sup>

**A2.5 UV/Vis-spectra** were recorded in 1-cm quartz cuvettes with a Cary 100 Conc UV/Vis spectrophotometer (Varian).

**A2.6 Combustion analyses** were performed with a Carlo Erba 1106 instrument (analytical laboratory, Universität Würzburg) and a vario Micro cube (analytical laboratory, Technische Universität Kaiserslautern).

**A2.7 Melting points** [ $^{\circ}\text{C}$ ] were determined on a Koffler hot-plate melting point microscope (*Reichert*) and are not corrected.

### A3 Reagents and Chromatography

**A3.1 Reagents:** Benzene, dimethyl formamide, dichloromethane, tetrahydrofuran and diethyl ether were purified and dried according to standard procedures.<sup>[2]</sup> All other reagents were used as received from commercial suppliers (Sigma Aldrich, Acros Organics, Fisher Scientific, Merck), unless otherwise indicated. 3-Hydroxy-4-methylthiazole-2(3*H*)-thione,<sup>[3]</sup> 3-hydroxy-4-methylthiazole-2(3*H*)-thione tetraethylammonium salt,<sup>[4]</sup> isopropyltriphenylphosphonium bromide,<sup>[5]</sup> diethyl azodicarboxylate (DEAD),<sup>[6]</sup> *trans*-hexahydrophthalic acid anhydride<sup>[7–9]</sup> were prepared according to published procedures.

**A3.2 Thin layer chromatography:** Reaction progress was monitored via thin layer chromatography (tlc) on aluminum sheets coated with silica gel (60 F<sub>254</sub>, Merck). Compounds on developed TLC-sheets were detected with the aid of the UV-VIS indicator commercially disposed on the sheets, showing colored or darker spots by illuminating developed sheets with a hand lamp emitting 254 nm light. Alternatively, developed TLC-sheets were stained by Ekkert's reagent and subsequently heated, leading to blue-green spots for organobromines, blue spots for alcohols and yellow spots for 3-alkenoxy-4-methylthiazole-2(3*H*)-thiones (e.g. **1**).

**A3.3 Column chromatography:** Geduran Si60-silica gel (40–63 µm) served as stationary phase for column chromatography (flash chromatography).

**A3.4 Gas chromatography coupled to mass spectrometry:** Mass spectra (EI, 70 eV) were recorded with a Mass Selective Detector HP 6890 (Hewlett Packard) connected to an Agilent-gaschromatograph.

## A4 Alkenols

**A4.1 *trans*-2-(Prop-2-en-1-yl)-cyclopentan-1-ol** was prepared from cyclopentene oxide and 2-propen-1-yl magnesium bromide.<sup>[10–12]</sup>  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.15–1.29 (m, 1 H), 1.49–1.64 (m, 2 H), 1.66–1.84 (m, 2 H), 1.85–1.97 (m, 2 H), 2.03 (dt,  $J_d = 13.9$  Hz,  $J_t = 7.1$  Hz, 1 H), 2.18 (dt,  $J_d = 14.0$  Hz,  $J_t = 6.9$  Hz, 1 H), 3.86 (q,  $J = 5.5$  Hz, 1 H), 4.95–5.13 (m, 2 H), 5.77–5.93 (m, 1 H). The spectrum showed no resonance for the hydroxyl proton.  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  21.6, 29.7, 34.3, 38.1, 47.6, 78.7, 115.6, 137.6.

**A4.2 *cis*-2-(Prop-2-en-1-yl)-cyclopentan-1-ol.** A solution of *p*-nitrobenzoic acid (7.35 g, 44.0 mmol), *trans*-2-(prop-2-en-1-yl)-cyclopentan-1-ol (2.06 g, 16.3 mmol), and triphenylphosphine (12.9 g, 49.0 mmol) in benzene (80 mL) was treated in a dropwise manner with diethyl azodicarboxylate (DEAD, 8.83 g, 49.0 mmol). The reaction mixture was stirred for four hours at 21 °C. The solvent was removed under reduced pressure to leave an oil, which was purified by column chromatography [diethyl ether/pentane = 1:20 (v/v)]. *cis*-2-(Prop-2-en-1-yl)cyclopent-1-yl 4-nitrobenzoate (3.58 g, 13.0 mmol, 80 %), yellowish liquid.  $R_f = 0.22$  for diethyl ether/pentane = 1:20 (v/v).  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 600 MHz)  $\delta$  1.53–1.61 (m, 1 H), 1.64–1.73 (m, 1 H), 1.83–1.90 (m, 2 H), 1.91–1.98 (m, 1 H), 2.02–2.12 (m, 2 H), 2.16 (dt,  $J_d = 14.2$ ,  $J_t = 7.3$  Hz, 1 H), 2.31 (dt,  $J_d = 13.9$ ,  $J_t = 7.0$  Hz, 1 H), 4.92–5.01 (m, 2 H), 5.45 (t,  $J = 4.8$  Hz, 1 H), 5.80 (ddt,  $J_d = 17.0$ , 10.1,  $J_t = 7.0$  Hz, 1 H), 8.17–8.20 (m, 2 H), 8.27–8.31 (m, 2 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 150 MHz)  $\delta$  22.0, 29.6, 32.5, 33.9, 44.3, 79.5, 115.6, 123.5, 130.5, 136.2, 137.1, 150.4, 164.2. Anal. **A4.6 *cis*-[2-(Ethenyl)-cyclohex-1-yl]-methanol**<sup>[16]</sup> was prepared from *cis*-8-oxabicyclo-[4.3.0]nonan-7-ol, obtained by the method of Lambert and co-workers as single diastereomer, and subsequent Wittig-alkenylation.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.27–1.81 (m, 10 H), 2.48 (dq,  $J_d = 8.6, J_q = 4.1$  Hz, 1 H), 3.36–3.58 (m, 2 H), 4.97–5.15 (m, 2 H), 6.05 (ddd,  $J = 17.1, 10.2, 8.9$  Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  22.3, 25.0, 25.2, 30.9, 41.0, 42.5, 65.5, 115.1, 139.3.

**A4.7 *trans*-[2-(Ethenyl)-cyclohex-1-yl]-methanol.** A solution of *trans*-1,2-cyclohexanedicarboxylic acid anhydride (5.00 g, 32.4 mmol) in tetrahydrofuran (15 mL) was added in a dropwise manner to a suspension of sodium borohydride (2.49 g, 65.8 mmol) in tetrahydrofuran (75 mL) at 0 °C. The reaction mixture was stirred for three hours in an ice bath, which was allowed to thaw (temperature of the ice bath after 3 hours: 15 °C). This mixture was cooled to 0 °C and *slowly* treated with methanol (10 mL). The rate of methanol addition thereby is crucial to prevent extensive gas evolution. The likewise obtained mixture was concentrated under reduced pressure (300 mbar/ 40 °C) to leave a residue, which was taken up in a mixture of brine (100 mL) and ethyl acetate (65 mL), and cooled to 0 °C. An aqueous 2 M solution of hydrochloric acid (32 mL, 64 mmol) was added to this mixture at 0 °C. The phases were separated. The cold aqueous layer was extracted rapidly with ethyl acetate (3 × 50 mL). Combined organic layers were washed with brine (70 mL) and concentrated under reduced pressure (200 mbar/ 40 °C) to leave a colorless solid (4.31 g, 27.2 mmol, 84 %), which was recrystallized from ethyl acetate (20 mL). *trans*-2-(Hydroxymethyl)-cyclohexanecarboxylic acid.<sup>[17,18]</sup> Yield 3.33 g (21.0 mmol, 65 %), colorless crystals. M.p. 99–100 °C.  $^1\text{H-NMR}$  ( $\text{DMSO}-d_6$ , 600 MHz)  $\delta$  0.94–1.04 (m, 1 H), 1.11–1.23 (m, 2 H), 1.28–1.37 (m, 1 H), 1.56 (tdt,  $J_t = 11.0, 3.8, J_d = 7.2$  Hz, 1 H), 1.66 (d,  $J = 9.2$  Hz, 2 H), 1.81 (d,  $J = 12.1$  Hz, 2 H), 1.97 (td,  $J_t = 11.4, J_d = 3.7$  Hz, 1 H), 3.16 (dd,  $J = 10.3, 7.0$  Hz, 1 H), 3.34 (dd,  $J = 10.3, 4.0$  Hz, 1 H), 4.34 (br. s., 1 H), 11.95 (br. s., 1 H).  $^{13}\text{C-NMR}$  ( $\text{DMSO}-d_6$ , 150 MHz)

$\delta$  25.0, 25.1, 28.1, 29.5, 41.0, 45.3, 64.1, 176.8. Anal. Calcd. for  $C_8H_{14}O_3$  (158.20): C, 60.74; H, 8.92; Found: C, 60.44; H, 9.22. *trans*-2-(Hydroxymethyl)-cyclohexanecarboxylic acid was treated with a catalytic amount of *p*-toluenesulfonic acid monohydrate to afford *trans*-8-oxabicyclo[4.3.0]nonan-7-one,<sup>[8,19]</sup> which was reduced with DIBAL-H to furnish *trans*-8-oxabicyclo[4.3.0]nonan-7-ol<sup>[16]</sup> as mixture of the hydroxyaldehyde and stereoisomeric lactols. *Lactol – major stereoisomer*.  $^1H$ -NMR ( $CDCl_3$ , 400 MHz)  $\delta$  0.95–2.04 (m, 9 H), 3.31 (dd,  $J = 10.8, 7.8$  Hz, 1 H), 3.43–3.45 (m, 1 H), 4.09 (t,  $J = 7.3$  Hz, 1 H), 5.30 (t,  $J = 4.0$  Hz, 1 H). The spectrum displayed no resonance for the hydroxyl proton.  $^{13}C$ -NMR ( $CDCl_3$ , 100 MHz)  $\delta$  24.8, 25.5, 25.6, 28.1, 40.4, 49.5, 72.5, 98.3. *Lactol – minor stereoisomer*.  $^1H$ -NMR ( $CDCl_3$ , 400 MHz)  $\delta$  0.95–2.04 (m, 9 H), 3.58 (dd,  $J = 11.0, 7.6$  Hz, 1 H), 3.90 (t,  $J = 7.0$  Hz, 1 H), 4.04–4.07 (m, 1 H), 5.07 (dd,  $J = 7.1, 5.9$  Hz, 1 H). The spectrum displayed no resonance for the hydroxyl proton.  $^{13}C$ -NMR ( $CDCl_3$ , 100 MHz)  $\delta$  24.8, 24.9, 25.8, 27.7, 39.9, 53.6, 66.6, 205.4. Wittig-alkenylation of *trans*-8-oxabicyclo[4.3.0]nonan-7-ol<sup>[16]</sup> in extension to the method described for the *cis*-isomer<sup>[16]</sup> in section 4.6 furnished *trans*-[2-(ethenyl)-cyclohex-1-yl]-methanol.  $^1H$ -NMR ( $CDCl_3$ , 400 MHz)  $\delta$  0.98–1.37 (m, 5 H), 1.52–1.87 (m, 6 H), 3.43 (dd,  $J = 11.0, 5.8$  Hz, 1 H), 3.60 (dd,  $J = 10.9, 4.7$  Hz, 1 H), 4.95 (dd,  $J = 10.1, 2.0$  Hz, 1 H), 5.03 (dd,  $J = 17.2, 2.0$  Hz, 1 H), 5.70 (dt,  $J_d = 17.2, J_t = 9.6$  Hz, 1 H).  $^{13}C$ -NMR ( $CDCl_3$ , 100 MHz)  $\delta$  25.7, 25.8, 29.1, 33.4, 44.3, 45.9, 67.1, 114.0, 143.8. Anal. Calcd. for  $C_9H_{16}O$  (140.22): C, 77.09; H, 11.50; Found: C, 76.54; H, 11.56.

**A4.8** *cis*-[2-(Methylprop-1-en-1-yl)-cyclohex-1-yl]-methanol was prepared in extension to the method described by Lambert<sup>[16]</sup> for *cis*-[2-(ethenyl)-cyclohex-1-yl]-methanol. In an atmosphere of nitrogen, isopropyltriphenylphosphonium bromide (2.90 g, 7.53 mmol) was suspended in dry tetrahydrofuran (30 mL) and cooled to 0 °C. *n*-Butyl lithium (4.7 mL, 7.52 mmol, 1.6 M in hexane) was added to this mixture in one portion at 0 °C. The resulting deep red-colored suspension was stirred for two and a half hours at 21 °C. Meanwhile *cis*-8-oxabicyclo[4.3.0]nonan-7-ol, was dissolved in dry tetrahydrofuran (20 mL) and treated at –78 °C with a solution of *n*-butyl lithium (3.0 mL, 4.8 mmol) in hexane (1.6 M). The reaction mixture was afterwards allowed to warm for three minutes to 0 °C, and was then cooled to

–78 °C again. To this mixture was added in a dropwise manner the solution of 2-propylidene triphenylphosphine in tetrahydrofuran within twenty-five minutes. The cooling bath was removed after complete addition of the phosphorous reagent, and the reaction mixture is allowed to warm to 21 °C. The reaction mixture was stirred for additional 5 hours at room temperature and then treated with a saturated aqueous ammonium chloride solution (40 mL) and water (40 mL). Phases were separated. The aqueous layer was extracted with diethyl ether (2 × 20 mL). Combined organic layers were washed with brine (60 mL) and concentrated under reduced pressure (800 mbar/ 40 °C) to afford an oily residue, which was purified by chromatography [diethyl ether/pentane = 1:1 (v/v)]. Yield: 679 mg (4.03 mmol, 80 %) colorless oil.  $R_f$  = 0.39 for diethyl ether/pentane = 1:1 (v/v).  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.26–1.38 (m, 2 H), 1.40–1.57 (m, 6 H), 1.64 (d,  $J$  = 1.2 Hz, 3 H), 1.67–1.75 (m, 2 H), 1.71 (d,  $J$  = 0.9 Hz, 3 H), 2.65–2.73 (m, 1 H), 3.38–3.48 (m, 2 H), 5.35 (dt,  $J_d$  = 10.1,  $J_t$  = 1.2 Hz, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  17.8, 22.1, 24.7, 25.3, 26.2, 31.7, 34.4, 43.0, 66.1, 124.1, 132.2. Anal. Calcd. for  $\text{C}_{11}\text{H}_{20}\text{O}$  (168.28): C, 78.51; H, 11.98; Found: C, 78.26; H, 11.88.

**A4.9 *trans*-[2-(Methylprop-1-en-1-yl)-cyclohex-1-yl]-methanol** was prepared according to the procedure outlined in section 4.7 for the *cis*-isomer.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.00–1.12 (m, 2 H), 1.19–1.32 (m, 3 H), 1.49–1.60 (m, 2 H), 1.63 (d,  $J = 1.6$  Hz, 3 H), 1.67–1.83 (m, 3 H), 1.63 (d,  $J = 1.6$  Hz, 3 H), 1.98 (qd,  $J_q = 10.5$ ,  $J_d = 3.8$  Hz, 1 H), 3.32–3.41 (m, 1 H), 3.56 (dd,  $J = 10.8$ , 5.0 Hz, 1 H), 4.96–5.02 (m, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  18.1, 25.8 (2C/HMQC), 25.9, 29.3, 33.4, 40.1, 45.2, 67.8, 130.0, 131.2. Anal. Calcd. for  $\text{C}_{11}\text{H}_{20}\text{O}$  (168.28): C, 78.51; H, 11.98; Found: C, 78.15; H, 12.07.

**A4.10 2-(1-Methylenecyclohex-2-yl)-ethan-1-ol** was prepared from cyclohexanone according to the method reported by Segre<sup>[20]</sup> and Gream<sup>[21]</sup>, and respective co-workers.  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.24–1.35 (m, 1 H), 1.40–1.58 (m, 4 H), 1.60–1.78 (m, 3 H), 1.85–1.97 (m, 1 H), 1.98–2.09 (m, 1 H), 2.17–2.29 (m, 2 H), 3.66 (t,  $J = 6.6$  Hz, 2 H), 4.60 (s, 1 H), 4.66 (s, 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  23.9, 28.7, 33.9, 34.4, 35.0, 39.8, 61.4, 105.9, 152.6.

**A4.11 (1-Methylcyclohex-1-en-4-yl)-methanol** was prepared from 2-methylbuta-1,3-diene (isoprene) and methyl acrylate in a Diels-Alder-reaction as described by Inukai and Kasai<sup>[22]</sup>, and reduction of *O*-methyl-(1-methylcyclohex-1-en-4-yl)-carboxylate by  $\text{LiAlH}_4$  according to Monti and co-workers.<sup>[23]</sup>  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  1.15–1.35 (m, 1 H), 1.39 (s, 1 H), 1.61–1.90 (m, 3 H), 1.65 (s, 3 H), 1.91–2.20 (m, 3 H), 3.41–3.63 (m, 2 H), 5.38 (br. s., 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  23.6, 25.6, 28.2, 29.5, 36.2, 67.9, 119.8, 134.1.

**A4.12 2-((1*S*,4*S*,5*R*)-2,6,6-Trimethylbicyclo[3.1.1]hept-2-en-4-yl)-ethanol** (verbenylethanol) was prepared by converting (*S*)-*cis*-verbenol into 2-((1*S*,4*S*,5*R*)-2,6,6-trimethylbicyclo[3.1.1]hept-2-en-4-yl)-ethenyl ether<sup>[24,25]</sup>  $\{[\alpha]_{\text{D}}^{25} = 98.0$  ( $c = 1.02/\text{ethanol}$ )}, followed by [1.3] sigmatropic rearrangement of the vinyl ether into 2-((1*S*,4*S*,5*R*)-2,6,6-trimethylbicyclo[3.1.1]hept-2-en-4-yl)-ethanal<sup>[26,27]</sup>  $\{[\alpha]_{\text{D}}^{25} = -74.6$  ( $c = 1.03/\text{ethanol}$ )}, and reduction of this aldehyde as follows. A suspension of 2-((1*S*,4*S*,5*R*)-2,6,6-trimethylbicyclo[3.1.1]hept-2-en-4-yl)-ethanal (650 mg, 3.63 mmol), lithium aluminium hydride (207 mg, 5.50 mmol) and diethyl ether (20 mL) was stirred for one hour at 20 °C, and carefully hydrolyzed by an aqueous solution of 2 M hydrochloric acid (10 mL). After phase separation, the aqueous layer was extracted with diethyl ether (3 × 20 mL). The organic phases from the reaction

mixture and combined organic washings were combined and concentrated under reduced pressure to leave a residue, which was purified by chromatography [diethyl ether/pentane = 1:1 (v/v), ( $R_f$  = 0.40)]. Yield: 480 mg (2.66 mmol, 73 %) colorless oil.  $[\alpha]_D^{25} = -85.8$  ( $c$  = 1.03/ethanol).  $^1\text{H-NMR}$  ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  0.85 (s, 3 H), 1.13 (d,  $J$  = 8.9 Hz, 1 H), 1.28 (s, 3 H), 1.33–1.45 (m, 1 H), 1.49–1.61 (m, 1 H), 1.63–1.69 (m, 4 H), 1.89–1.99 (m, 2 H), 2.18 (dt,  $J_d$  = 8.7,  $J_t$  = 5.7 Hz, 1 H), 2.31–2.42 (m, 1 H), 3.71 (t,  $J$  = 6.8 Hz, 2 H), 5.14 (br. s., 1 H).  $^{13}\text{C-NMR}$  ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  20.4, 22.9, 26.5, 27.9, 36.3, 36.6, 40.6, 45.1, 47.6, 61.3, 112.0, 144.8. Anal. Calcd. for  $\text{C}_{12}\text{H}_{20}\text{O}$  (180.29): C, 79.94; H, 11.18; Found: C, 79.95; H, 11.08.

## A5 4-Toluenesulfonic Acid *O*-Esters from Alkenols

**A5.1 General method.** A solution of an alkenol (1 mmol), 1,4-diazabicyclo[2.2.2]octane (DABCO, 2 mmol) in dichloromethane (2 mL) was cooled in an ice-bath to 0 °C and treated with 4-toluenesulfonyl chloride (1.5 mmol) in portions over a period of 5 min. The slurry was stirred for 2 hours at 20 °C and diluted with dichloromethane (8 mL) to afford a suspension which was washed with aqueous 2 M aqueous hydrochloric acid (10 mL) and a saturated aqueous solution of NaHCO<sub>3</sub> (10 mL). The organic layer was separated, dried (MgSO<sub>4</sub>), and concentrated under reduced pressure. The remaining oil was purified by chromatography (SiO<sub>2</sub>).

**A5.2 *trans*-[2-(Prop-2-en-1-yl)-cyclopent-1-yl] 4-toluenesulfonate**<sup>[28]</sup> was prepared from *trans*-2-(prop-2-en-1-yl)cyclopentan-1-ol (545 mg, 4.32 mmol) according to procedure 5.1. Eluent used for chromatographic purification: diethyl ether/pentane = 1:3 (v/v). Yield: 1.16 g (4.14 mmol, 96 %), colorless liquid. *R*<sub>f</sub> = 0.53 for diethyl ether/pentane = 1:3 (v/v). <sup>1</sup>H-NMR (CDCl<sub>3</sub>, 400 MHz) δ 1.13–1.23 (m, 1 H), 1.52–1.64 (m, 1 H), 1.64–1.73 (m, 1 H), 1.74–1.81 (m, 2 H), 1.81–1.92 (m, 2 H), 1.99–2.14 (m, 2 H), 2.44 (s, 3 H), 4.48–4.57 (m, 1 H), 4.84–4.94 (m, 2 H), 5.48–5.67 (m, 1 H), 7.33 (d, *J* = 8.3 Hz, 2 H), 7.78 (d, *J* = 8.3 Hz, 2 H). <sup>13</sup>C-NMR (CDCl<sub>3</sub>, 150 MHz) δ 21.6, 22.2, 28.9, 31.9, 36.8, 45.1, 88.4, 116.3, 127.8, 129.7, 134.3, 135.9, 144.4. **A5.13 2-[(1*S*,4*S*,5*R*)-2,6,6-Trimethylbicyclo[3.1.1]hept-2-en-4-yl]-ethyl 4-toluenesulfonate** was prepared from 2-[(1*S*,4*S*,5*R*)-2,6,6-trimethylbicyclo[3.1.1]hept-2-en-4-yl]-ethan-1-ol (440 mg, 2.44 mmol) according to procedure 5.1. Eluent used for chromatographic purification: diethyl ether/pentane = 1:1 (v/v). Yield: 690 mg (2.06 mmol, 85 %), yellowish liquid.  $R_f = 0.71$  for diethyl ether/pentane = 1:1 (v/v).  $[\alpha]_{\text{D}}^{25} = -38.9$  ( $c = 1.01/\text{ethanol}$ ).  $^1\text{H}$ -NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  0.78 (s, 3 H), 0.99–1.06 (m, 1 H), 1.23 (s, 3 H), 1.53–1.64 (m, 1 H), 1.61 (s, 3 H), 1.64–1.79 (m, 2 H), 1.92 (t,  $J = 5.1$  Hz, 1 H), 2.12 (dt,  $J_{\text{d}} = 8.9$ ,  $J_{\text{t}} = 5.6$  Hz, 1 H), 2.23–2.31 (m, 1 H), 2.45 (s, 3 H), 4.03–4.14 (m, 2 H), 4.94 (br. s., 1 H), 7.35 (d,  $J = 8.2$  Hz, 2 H), 7.80 (d,  $J = 8.2$  Hz, 2 H).  $^{13}\text{C}$ -NMR ( $\text{CDCl}_3$ , 150.9 MHz)  $\delta$  20.4, 21.6, 22.9, 26.4, 27.7, 32.4, 35.9, 40.7, 44.6, 47.5, 69.1, 118.8, 127.9, 129.8, 133.2, 144.6, 145.6.

## A6 Bromocyclization with *N*-Bromosuccinimide

**A6.1 Bromocyclization of *trans*-2-(prop-2-en-1-yl)-cyclopentan-1-ol.** A solution of *trans*-2-(prop-2-en-1-yl)-cyclopentan-1-ol (126 mg, 1.00 mmol) in dichloromethane (5 ml) was treated at room temperature in small portions with *N*-bromosuccinimide (267 mg, 1.50 mmol). The resulting suspension was stirred for 14 days at room temperature (~20 °C). Solids were filtrated off and the filtrate washed with an aqueous saturated solution of sodium thiosulfate (10 mL). The aqueous washing was extracted with petroleum ether (4 × 20 mL). Combined organic layers were dried (MgSO<sub>4</sub>) and concentrated under reduced pressure to furnish a residue, which was purified by column chromatography on SiO<sub>2</sub> as stationary phase and a 9/1-mixture (v/v) of petroleum ether/diethyl ether as eluent. **1,4-*trans*-4,6-*cis*-4-Brom-2-oxabicyclo[4.3.0]nonane.** Yield 40 mg (20 %), yellow oil, *R*<sub>f</sub> = 0.59 [petroleum ether /diethyl ether = 9/1 (v/v)]. <sup>1</sup>H-NMR (CDCl<sub>3</sub>, 250 MHz): δ = 1.07–1.31 (m, 1 H), 1.36–1.81 (m, 6 H), 1.83–2.00 (m, 1 H), 2.49–2.68 (m, 1 H), 3.14–3.29 (m, 1 H), 3.55 (t, <sup>3</sup>*J* = 10.5 Hz, 1 H), 3.99–4.20 (m, 2 H). <sup>13</sup>C-NMR (CDCl<sub>3</sub>, 63 MHz) δ 19.6, 26.3, 28.0, 41.0, 45.5, 46.1, 73.6, 83.9. ## A8 Computational Chemistry

### A8.1 Computational Details

All calculations were carried out with Gaussian03<sup>[31]</sup>, using the density functional/Hartree-Fock hybrid models B3LYP and BHandHLYP and split valence double- $\zeta$  basis set 6-31+G(d,p) and split valence triple- $\zeta$  basis set 6-311G(d,p). No symmetry or internal coordinate constraints were applied during energy function minimization. The ultrafine grid in combination with the tight option for energy function minimization was used. The absence of imaginary modes of vibration characterized computed structures as minima (for radicals **I**, **II**, and **VII** and for propene). Transition structures **TS-I** and **TS-VII** were located with the Berny algorithm. Hessian matrices of transition structures had exactly one negative stretching mode (Table 9 of the associated manuscript). Animations of eigenvector coordinates using Molden<sup>[32]</sup> were performed to verify that the imaginary mode correlates with the trajectory of C,O bond formation. Approximate Gibbs free energies ( $G^{298.15}$ ) were obtained through thermochemical analysis for 298.15 K by unscaled frequency calculation from the thermal correction reported by Gaussian03. Likewise obtained Gibbs free energies take into account zero-point correction, thermal correction, and entropy. All transition structures were maxima on electronic potential energy hypersurface, which may not correspond to maxima on the free energy surface.

### 8.2 Ball-and-Stick Graphics from Modelled Structures

Graphics displaying computed equilibrium structures of oxygen radicals, addition products, and transition structures associated with oxygen radical additions were generated from B3LYP-calculated atomic coordinates. The results obtained from BHandHLYP-calculations provided almost identical conformations for the investigated structures. Oxygen is depicted in the ball-and-stick models in red, carbon in gray and hydrogen in white.

**Table A1.** Calculated zero point vibrational energy (ZPVE)-corrected electronic energies ( $E$ , 0 K) expectation values of spin the operator  $\langle S^2 \rangle$  and free energies ( $G$ , 298.15K) for the 2-(cyclohexen-3-yl)-ethoxyl radical cyclization **li**  $\rightarrow$  **lii**.

TWO ROADS DIVERGED IN A WOOD, AND I--  
 I TOOK THE ONE LESS TRAVELED BY,  
 AND THAT HAS MADE ALL THE DIFFERENCE.  
 -- ROBERT FROST

## A9 Crystallography

The applied model for solving the crystal structure uses restraints for fixing carbons 2 and 4, nitrogen N3/N3a, and oxygen 1/1a in a plane. Treating residual electron density as systematic disordering leads to a 78/22-ratio of diastereomers of 3-[(1-methylcyclohex-1-en-4-yl)-methoxy]-4-methylthiazole-2(3*H*)-thione (**1g**) at crystallographic independent positions. The diastereomers differ in configuration at C8 and C8a with respect to configuration at the stereogenic N,O-bond. The minor diastereomer (population of 22%) is depicted in Figure A146 and the major (population of 78%) in Figure 2 of the associated article.

**Figure A146.** Ellipsoid graphic of (*S,P*)/(*R,M*)-3-[(1-methylcyclohex-1-en-4-yl)-methoxy]-4-methylthiazole-2(3*H*)-thione (*S,P*)/(*R,M*)-(**1g**) in the solid state [minor diastereomer at 150 K; the (*S,P*)-isomer was arbitrarily chosen from the racemate for presentation (50% probability level); hydrogen atoms are drawn as circles of an arbitrary radius; oxygen is depicted in red, nitrogen in blue, and sulfur in orange; for depiction of the minor diastereomer see the ESI].

**B1 General Remarks:** (i) The compound numbering in the Supplementary data is consistent with that of the associated publication. (ii) References refer exclusively to the Supplementary data. (iii) All compounds used in this study were racemic.

## B2 Instrumentation

Melting points [°C] were determined on an *Electrothermal* 9100 instrument. Values were not corrected.

$^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were recorded with FT-NMR DPX 200, DPX 400 and DMX 600 instruments (*Bruker*). Chemical shifts refer to the  $\delta$ -scale. The resonances of residual protons and those of carbons of deuterated solvent molecules  $\text{CDCl}_3$  ( $\delta_{\text{H}}$  7.26,  $\delta_{\text{C}}$  77.0),  $\text{C}_6\text{D}_6$  ( $\delta_{\text{H}}$  7.16,  $\delta_{\text{C}}$  128.06) served as internal standard.

Mass spectra (EI, 70 eV) were recorded with a Mass Selective Detector HP 6890 (*Hewlett Packard*).

UV/Vis spectra were recorded with a Perkin Elmer UV/Vis 330 spectrometer and a Cary 100 Conc spectrometer (VARIAN).

Reaction progress was monitored via thin layer chromatography (tlc) on aluminum sheets coated with silica gel (60 F<sub>254</sub>, *Merck*). Compounds were detected on developed tlc sheets via UV-light absorption (254 nm) or staining with a solution of Ekkert's reagent, prepared from anisaldehyde (15 g), EtOH (250 mL), and conc.  $\text{H}_2\text{SO}_4$  (2.5 mL).<sup>[1]</sup>

Combustion analysis was performed with a Carlo Erba 1106 instrument (analytical laboratory, Universität Würzburg) and a vario Micro cube (analytical laboratory, Technische Universität Kaiserslautern).

Photochemical reactions were performed in a Southern New England Rayonet<sup>®</sup> chamber reactor equipped with 12 light bulbs ( $\lambda = 350\text{ nm}$ ). The photoreactor was ventilated from the bottom in order to maintain approximately 25 °C inside the cavity. Stirring was achieved with a micro magnetic stirring device.

### B3 Reagents

Copper(I)-chloride (Stem Chemicals, anhydrous, 97%+), DIC (Aldrich Chemicals, 99%), 2-methylpropan-2-ol (**3a**) (Riedel-de Haen 99%), 2-methylbutan-2-ol (**3b**) (Merck Chemicals, 99%) and 2-phenylpropan-2-ol (**3d**) (Acros Chemicals 99%) were commercially available. 2-Methyl-5-phenylpentan-2-ol (**3c**),<sup>[2]</sup> 2-(4-chlorophenyl)-2-propanol (**3e**),<sup>[3,4]</sup> and 2-phenylhex-5-en-2-ol (**3f**)<sup>[5,6]</sup> were prepared according to published procedures. Column chromatography was performed on SiO<sub>2</sub> (Fluka, 0.04–0.063 mm) as stationary phase. Petroleum ether referred to the fraction boiling between 40–55°C. All solvents were purified according to standard procedures.<sup>[7]</sup>

### B4 3-Alkoxythiazole-2(3H)-thione Reactions

**B4.1 Thermal decomposition of 3-cumyloxythiazolethione 1d.** A solution of 3-cumyloxythiazolethione **1d** (185 mg, 0.50 mmol) in dry toluene (6 mL) was heated under reflux for 1 h. The solution was subjected to GC-analysis for identification of volatile products. *α*-Methylstyrene **6**. Yield: 46.1 mg (78%). Phenyl methyl ketone (**7**). Yield: 1.8 mg (3%). Concentration of the solution under reduced pressure (100 → 20 mbar, 40 °C) afforded an oil that was purified by column chromatography [elution gradient *tert*-butyl methyl ether:pentane = 1:1 → *tert*-butyl methyl ether:acetone = 1:1 (v/v)]. 1,2-Bis-[5-(4-methoxyphenyl)-4-methylthiaz-3-yl]-disulfane (**5**).<sup>[8]</sup> Yield: 65.0 mg (27%), yellow solid, mp 87 °C. *R*<sub>f</sub> = 0.30 for *tert*-butyl methyl ether:pentane = 1:1 (v/v). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz) δ 2.44 (s, 6H), 3.83 (s, 6H), 6.93 (d, 4H, *J* = 9.0 Hz), 7.32 (d, 4H, *J* = 8.7 Hz), <sup>13</sup>C NMR (CDCl<sub>3</sub>, 101 MHz) δ 16.1, 55.3, 114.2, 123.5, 130.4, 136.0, 149.0, 159.6, 160.4. 5-(*p*-Methoxyphenyl)-4-methylthiazole-2(3H)-thione **8**.<sup>[9]</sup> Yield 6.6 mg (6%), colorless crystals. *R*<sub>f</sub> = 0.53 for *tert*-butyl methyl ether:acetone = 1:1 (v/v). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz) δ 2.18 (s, 3H), 3.82 (s, 3H), 6.91 (d, 2H, *J* = 8.6 Hz), 7.25 (d, 2H, *J* = 6.6 Hz), 9.98 (s, 1H). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 101 MHz) δ 12.7, 55.3, 113.9, 114.2, 124.1, 124.8, 129.9, 159.1, 174.2.

#### B4.2 Thermal conversion of 3-(2-methyl-5-phenylpent-2-oxo)-thiazole-2(3H)-thione 1c.

An oxygen-free solution of 3-alkoxythiazolethione **1c** (207 mg, 500 μmol), BrCCl<sub>3</sub> (988 mg, 5.00 mmol, 0.49 mL), and AIBN (spatula tip) in C<sub>6</sub>H<sub>6</sub> (6.0 mL) was boiled under reflux in an atmosphere of Ar. AIBN was added in small portions (spatula tip) until complete

consumption of starting material **1c** had occurred (tlc). The reaction mixture was allowed to cool to 20 °C and was concentrated under reduced pressure (100 → 20 mbar, 40 °C). The residue was purified by column chromatography using pentane:Et<sub>2</sub>O = 10:1 (v/v) as eluent. *2,2-Dimethyl-5-phenyltetrahydrofuran (10)*.<sup>[10]</sup> Yield: 53.6 mg (61%), colorless liquid. *R*<sub>f</sub> = 0.80 for pentane:Et<sub>2</sub>O = 10:1 (v/v).

### B4.3 Analytical scale reactions (NMR analysis)

**B4.3.1 Photochemical conversion.** A solution of 3-alkoxythiazolethione **1c** (16.9 mg, 40.9 μmol) and BrCCl<sub>3</sub> (169 mg, 0.85 mmol) in C<sub>6</sub>D<sub>6</sub> (0.50 mL) was prepared as described in section 4.3.1 of the associated publication. The solution was photolyzed for 45 min at 25 °C and left for additional 48 h at that temperature. It was checked in intervals for changes in **9/10**-ratios (<sup>1</sup>H NMR) using *p*-bromobenzaldehyde (*δ* = 9.41) as internal standard: *2,2-Dimethyl-5-phenyltetrahydrofuran (10)*.<sup>[10]</sup> Yield: 1.6 mg (22%, after 2 h), 3.3 mg (46%, after 48 h). <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>, 400 MHz) *δ* 1.24 (s, 3H), 1.28 (s, 3H), 1.46–1.58 (m, 2H), 1.62–1.72 (m, 1H), 1.96–2.03 (m, 1H), 4.88 (t, 1H, *J* = 7.5 Hz), 7.09–7.13 (m, 1H), 7.20–7.24 (m, 2H), 7.39–7.40 (m, 2H). <sup>13</sup>C NMR (C<sub>6</sub>D<sub>6</sub>, 151 MHz) *δ* 28.5, 29.2, 35.9, 39.1, 80.4, 80.9, 126.0, 127.2, 128.5, 144.7. *5-Bromo-2-methyl-5-phenylpentan-2-ol (9)*. Yield: 4.3 mg (44%, after 2 h), 0.5 mg (5%, after 48 h). <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>, 600 MHz) *δ* 0.92 (s, 3H), 0.93 (s, 3H), 1.14–1.19 (m, 1H), 1.44–1.49 (m, 1H), 2.10–2.18 (m, 1H), 2.26–2.32 (m, 1H), 4.73 (t, 1H, *J* = 7.6 Hz), 7.0–7.08 (m, 3H), 7.20–7.21 (m, 2H). <sup>13</sup>C NMR (C<sub>6</sub>D<sub>6</sub>, 151 MHz) *δ* 29.3, 29.5, 35.3, 43.6, 56.3, 69.7, 127.6, 128.3, 128.8, 142.7.

**B4.3.2 Thermal conversion.** A solution of 3-alkoxythiazolethione **1c** (20.7 mg, 50.0 μmol) and BrCCl<sub>3</sub> (98.8 mg, 500 μmol, 0.05 mL) in C<sub>6</sub>D<sub>6</sub> (0.60 mL) was prepared and treated as described in procedure 4.2. *2,2-Dimethyl-5-phenyltetrahydrofuran (10)*.<sup>[10]</sup> Yield: 7.40 mg (84%), determined via <sup>1</sup>H NMR versus anisole (*δ* = 3.29) as internal standard.

### B4.4 Thermally conversion of 3-(1-methyl-1-phenylpent-4-enyl-1-oxy)-thiazole-thione **1f**.

A solution of thiazolethione **1f** (90.0 mg, 219 μmol) and BrCCl<sub>3</sub> (434 mg, 2.19 mmol, 0.22 mL) was prepared and treated as described in procedure 4.2. Reaction time: 30 min. Products identified from the reaction mixture (GC/MS versus authentic references and *n*-decane as

internal standard). *Phenyl methyl ketone* (**7**). Yield: 2.71 mg (10%). *2-Phenyl-5-hexene-2-ol* (**3f**).<sup>[4,5]</sup> Yield: 8.37 mg (21%). MS (EI)  $m/z$  176 (<1), 158 (32), 143 (93), 129 (94), 121 (93), 115 (100), 105 (28)]. Eluent used for chromatographic purification: pentane:Et<sub>2</sub>O = 10:1 (v/v). *2-Methyl-2-phenyl-5-bromomethyl-tetrahydrofuran* (**13**).<sup>[11]</sup> Yield: 35.1 mg (63%), yellowish liquid, 73/27-mixture of cis/trans-isomers.  $R_f$  = 0.50 for pentane:Et<sub>2</sub>O = 10:1 (v/v).

**B4.5 Conversion of 3-cumyloxythiazolethione **1d** in the presence of norbornene **14**.** 3-cumyloxythiazolethione **1d** (190 mg, 510  $\mu$ mol) was treated as described in procedure 4.3.1 of the associated publication. *2-Bromo-3-trichloro-methylbicyclo[2.2.1]heptane* (**17**). Yield: 1.38g (92%), colorless oil, 5/95-mixture of 2-*exo*-3-*exo*/2-*endo*-3-*exo*-isomers.<sup>[12]</sup> *2-Bromo-3-(2-phenyl-prop-2-oxy)-bicyclo[2.2.1]heptane* (**16d**). Yield: 73.5 mg (46%), pale yellow oil, 28/72-mixture of 2-*exo*-3-*exo*/2-*endo*-3-*exo*-isomers.  $R_f$  = 0.47 for pentane:Et<sub>2</sub>O = 20:1 (v/v). Anal. Calcd. for C<sub>16</sub>H<sub>21</sub>OBr (309.24): C, 62.14; H, 6.84; Found: C, 61.78; H, 6.97. *2-endo*-3-*exo*-(**16d**). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz)  $\delta$  0.93–0.99 (m, 1H), 1.31–1.34 (m, 1H), 1.36–1.49 (m, 2H), 1.54 (s, 3H), 1.59 (s, 3H), 1.73–1.83 (m, 2H), 2.05–2.06 (m, 1H), 2.36–2.39 (m, 1H), 3.20–3.22 (m, 1H), 3.99–4.01 (m, 1H), 7.23–7.27 (m, 1H), 7.32–7.36 (m, 2H), 7.45–7.46 (m, 2H). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 151 MHz)  $\delta$  24.0, 24.6, 29.1, 29.6, 34.5, 42.8, 44.2, 63.1, 77.3, 84.4, 126.1, 126.9, 128.1, 146.6. MS (EI)  $m/z$  229 (6), 175 (4), 120 (43), 119 (100), 103 (9). *2-exo*-3-*exo*-(**16d**). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz)  $\delta$  0.85–0.92 (m, 1H), 0.99–1.06 (m, 1H), 1.12–1.15 (m, 1H), 1.32–1.41 (m, 1H), 1.47–1.53 (m, 1H), 1.58 (s, 3H), 1.59 (s, 3H), 2.05–2.06 (m, 1H), 2.13–2.14 (m, 1H), 2.47–2.48 (m, 1H), 3.11 (dd, 1H,  $J$  = 5.6, 1.2 Hz), 3.93 (dd, 1H,  $J$  = 6.4, 1.9 Hz), 7.23–7.26 (m, 1H), 7.32–7.36 (m, 2H), 7.52–7.55 (m, 2H). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 150 MHz)  $\delta$  25.5, 27.0, 28.7, 33.6, 44.2, 46.5, 61.6, 76.5, 78.6, 126.4, 126.8, 128.0, 147.0. MS (EI)  $m/z$  229 (6), 175 (4), 120 (43), 119 (100), 103 (9).

**B4.6 Conversion of 3-(4-chlorocumyloxy)-thiazolethione **1e** in the presence norbornene **14**.** 3-(*p*-Chlorocumyloxy)-thiazolethione **1e** (207 mg, 510  $\mu$ mol) was treated as described in procedure 4.3.1 of the associated publication. *2-Bromo-3-trichloro-methylbicyclo[2.2.1]heptane* (**17**). Yield: 1.43 g (93%), colorless oil, 7/93-mixture of 2-*exo*-3-*exo*/2-*endo*-3-*exo*-isomers.<sup>[12]</sup> *2-endo*-3-*exo*-2-Bromo-3-[2-(4-chlorophenyl)-prop-2-oxy]-bicyclo[2.2.1]heptane 2-*endo*-3-*exo*-(**16e**). Yield: 49.2 mg (28%), colorless oil.  $R_f$  = 0.46 for pentane:Et<sub>2</sub>O = 20:1 (v/v). *2-Bromo-3-[2-(4-chlorophenyl)-prop-2-oxy]-bicyclo[2.2.1]heptane* (**16e**). Yield:

27.7 mg (16%), colorless oil, 75/25-mixture of 2-*exo*-3-*exo*/2-*endo*-3-*exo*-isomers.  $R_f$  = 0.45 for pentane:Et<sub>2</sub>O = 20:1 (v/v). Anal. Calcd. for C<sub>16</sub>H<sub>20</sub>OBrCl (343.68): C, 55.92; H, 5.87; Found: C, 56.04; H, 5.98. 2-*endo*-3-*exo*-(**16e**). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz)  $\delta$  0.94–1.00 (m, 1H), 1.31–1.34 (m, 1H), 1.37–1.48 (m, 2H), 1.51 (s, 3H), 1.55 (s, 3H), 1.73–1.81 (m, 2H), 2.04 (d, 1H,  $J$  = 4.7 Hz), 2.38–2.40 (m, 1H), 3.18 (t, 1H,  $J$  = 2.0 Hz), 3.97–3.98 (m, 1H), 7.29–7.31 (m, 2H), 7.37–7.39 (m, 2H). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 151 MHz)  $\delta$  23.9, 24.6, 29.2, 29.5, 34.5, 42.7, 44.2, 62.8, 84.6, 127.6, 128.2, 132.7, 145.3. <sup>13</sup>C NMR (C<sub>6</sub>D<sub>6</sub>, 151 MHz)  $\delta$  24.2, 24.6, 28.9, 29.7, 34.5, 43.0, 44.5, 63.0, 77.0, 84.8, 127.8, 128.2, 133.1, 145.6. ## B5 Application of the *p*-Chlorocumyloxy-“Radical Clock”

### B5.1 Kinetic model

Formation of products **15** and **16e** from 3-(*p*-chlorocumyloxy)-thiazole-2(3*H*)-thione **1e**, bicyclohept[2.2.1]heptene (**14**), and BrCCl<sub>3</sub> according to a general mechanistic model<sup>[13]</sup> was assumed to occur via elementary reactions described in equations 1–4 (An = 4-H<sub>3</sub>CO-C<sub>6</sub>H<sub>4</sub>, CP = 4-Cl-C<sub>6</sub>H<sub>4</sub>).

Formation of *p*-chlorocumyloxy radical-derived products **15** and **16e** for analysis (GC), according to the model, was expressed by eqs. 5–6. Application of Bodenstein’s quasi-stationary principle<sup>[14]</sup> allowed us to transform eq. 6 by replacing [*exo-Vle*] via eq. 7a into eq. 6a. Division eq. 6a by eq. 5, and integration of differential eq. 8a provided analytical expression eq. 8b used for determining  $k^{A_R}_{1e}$  on the basis of known value  $k^{D_R}_{1e} = 1.1 \times 10^6 \text{ s}^{-1}$  (in CH<sub>3</sub>CN, 23 °C)<sup>[15]</sup> in section 5.2.

$$\frac{d [ \mathbf{15} ]}{dt} = k_{\text{le}}^{\text{D}_R} [ \mathbf{le} ] \quad (\text{eq. 5})$$

$$\frac{d [ \mathbf{16e} ]}{dt} = k_{\text{Br}} [ \text{exo-Vle} ] [ \text{BrCCl}_3 ] \quad (\text{eq. 6})$$

$$\frac{d [ \text{exo-Vle} ]}{dt} = k_{\text{le}}^{\text{A}_R} [ \mathbf{le} ] [ \mathbf{14} ] - k_{\text{Br}} [ \text{exo-Vle} ] [ \text{BrCCl}_3 ] = 0 \quad (\text{eq. 7})$$

$$[ \text{exo-Vle} ] = \frac{k_{\text{le}}^{\text{A}_R} [ \mathbf{le} ] [ \mathbf{14} ]}{k_{\text{Br}} [ \text{BrCCl}_3 ]} \quad (\text{eq. 7a})$$

eq. 7a  $\rightarrow$  eq. 6

2	0.105	29.5	29.5	29.5 (24:76)	1.00
3	0.050	37.5	26.5	12.0 (22:78)	0.45

<sup>a</sup> 3-*exo*-configuration for both stereoisomers.

**Figure B1.** Plot of product ratio **16e:15** vs. norbornene concentration  $\{[\mathbf{16e}]:[\mathbf{15}] = (9.331 \text{ M}^{-1})[\mathbf{14}] - 0.002$ ; correlation coefficient ( $R^2$ ) = 0.9997}.

Rate constant  $k_{\text{le}}^{\text{A}^{\text{Rcis}}}$  was calculated from the slope of the correlation obtained in Figure B1 on the basis of eq. 8b.

$$k_{\text{le}}^{\text{A}^{\text{R}}} = 9.331 \text{ M}^{-1} \quad k_{\text{le}}^{\text{D}^{\text{R}}} = 1.03 \times 10^7 \text{ M}^{-1}\text{s}^{-1}$$

## B6 Variable Temperature NMR Spectroscopy – Barrier to N,O-Rotation

### B6.1 Experimental

A solution of *p*-chlorocumyloxythiazolethione **1e** (35–40 mg) in CDCl<sub>3</sub> (0.5 mL, 99.8 atom%, filtrated through basic Al<sub>2</sub>O<sub>3</sub>) was thermostated (15 min) at a preselected temperature, chosen at the instrument panel of the NMR spectrometer. The temperature inside the cavity was measured with a MeOH NMR–thermometer.<sup>[16,17]</sup>

**Table B2.** Temperaturedependent chemical shifts of selected protons in *p*-chlorocumyl ester **1e** (600.13 MHz, CDCl<sub>3</sub>).

**1e**

entry	<i>T</i> / °C <sup>a</sup>	δ <sub>1'-CH<sub>3</sub></sub>	δ <sub>1''-CH<sub>3</sub></sub>	δ <sub>4-CH<sub>3</sub></sub>

7	20		1.99	1.65

<sup>a</sup> referenced versus the MeOH NMR thermometer. <sup>b</sup> signal coalescence

## B6.2 Barrier to N,O-Rotation

The rate constant  $k^c$  for exchange of nuclei from two equally populated positions at coalescence temperature  $T_c$  can be approximated with eq. 9, whereby  $\nu_a$  and  $\nu_b$  denote resonance frequencies of associated nuclei at slow exchange.<sup>[18]</sup>

$$k^c = \frac{\pi (\nu_a - \nu_b)}{\sqrt{2}} \quad (\text{eq. 9})$$

$k^c$  = rate of topomerization at  $T_c$

$$(\nu_a - \nu_b) = \Delta\delta 600.13 \text{ s}^{-1} = 132.1 \text{ s}^{-1}$$

$$k^c = 293.4 \text{ s}^{-1}$$

The Gibbs free energy of activation of the process can be derived from the rate constant  $k^c$  of topomerization at coalescence temperature  $T_c$  via the Eyring equation (eq. 10).

$$\Delta G_{T_c}^\ddagger = -RT \ln \frac{k_c h}{k^b \kappa T_c} \quad (\text{eq. 10})$$

$\kappa$  = transmission coefficient  $\sim 1$

$k^b$  = Boltzmann constant =  $1.381 \times 10^{-23} \text{ J K}^{-1}$

$h$  = Planck constant =  $6.626 \times 10^{-34} \text{ J s}$

$T_c = 270 \text{ K}$

$$\Delta G_{T_c}^\ddagger = -2.24 \text{ kJ mol}^{-1} \ln \frac{1.94 \cdot 10^{-31}}{3.73 \cdot 10^{-21}}$$

$$\Delta G_{T_c}^\ddagger = 53 \text{ kJ mol}^{-1}$$

## B7 N–O/C=S Bond Length Correlation – Solid State Chemistry

## B8 Computational Chemistry

### B8.1 Computational Details

All calculations were carried out with Gaussian03<sup>[21]</sup>, using the density functional/Hartee-Fock hybrid models B3LYP and BHandHLYP, and split valance double- $\zeta$  basis set 6-31+G(d,p), and split valence triple- $\zeta$  basis set 6-311G(d,p). No symmetry or internal coordinate constraints were applied during energy function minimization. The ultrafine grid in combination with the tight option for energy function minimization was used. The absence of imaginary modes of vibration characterized computed structures as minima (for radicals **I** and **VII**). Transition structures *exo/endo-VI* were located with the Berny algorithm. Hessian matrices of transition structures had exactly one negative stretching mode (Table 4 of the associated manuscript). Animations of eigenvector coordinates using Molden<sup>[22]</sup> were performed to verify that the imaginary mode correlated with the trajectory of C,O bond formation. Approximate Gibbs free energies ( $G_{298.15}$ ) were obtained through thermochemical analysis for 298.15 K by unscaled frequency calculation from the thermal correction reported by Gaussian03. Likewise obtained Gibbs free energies took into account zero-point correction, thermal correction, and entropy. All transition structures were maxima on electronic potential energy hypersurface, which may not correspond to maxima on the free energy surface.

B3LYP- and BHandHLYP-calculated equilibrium and transition structures differed slightly but not notably. For presentation, Ball-and-stick models of B3LYP-structures were selected in the following sections. Oxygen atoms are depicted in red, carbons in gray and hydrogens in white.

**Table B4.** Calculated zero-point vibrational energy (ZPVE)-corrected electronic energies ( $E$ , 0 K), expectation values of the spin operator  $\langle S^2 \rangle$  (for radicals), and Gibbs free energies ( $G$ , 298.15K) for alkoxy radical additions to norbornene **14**

## C1 General Remarks

**C1.1 Numbering of compounds:** Numbering of compounds in the *Electronic Supporting Information* and the accompanying publication are consistent.

**C1.2 References:** References refer exclusively to the *Electronic Supporting Information*.

## C2 Instrumentation

**C2.1 Nuclear magnetic resonance (NMR)-spectroscopy:** Proton- and carbon-13-NMR spectra were measured with Avance I 200, DPX 400, Avance I 600 instruments (*Bruker*). Chemical shifts refer to the  $\delta$ -scale. Proton resonances of residual non-deuterated solvents and carbon chemical shifts of  $\text{CDCl}_3$  ( $\delta_{\text{H}}$  7.26,  $\delta_{\text{C}}$  77.0),  $\text{C}_6\text{D}_6$  ( $\delta_{\text{H}}$  7.16,  $\delta_{\text{C}}$  128.06),  $\text{DMSO}[d_6]$  ( $\delta_{\text{H}}$  2.50,  $\delta_{\text{C}}$  39.52) were used as internal standards.

**C2.2 Infrared (IR)-spectroscopy:** All spectra were measured with a Bruker Vertex 80v FTIR spectrometer with a vacuum tight liquid cell (Bruker A140). The cell is composed of housing, KBr-windows, separated by two Mylar<sup>®</sup> spacers with a variable thickness of 0.006 to 0.5 millimeters and several seal rings. The sample cell with a path length of 0.075 millimeters is filled with a millimolar solution of the respective substance dissolved in acetonitrile and positioned inside the argon purged sample compartment. An average of 50 spectra at a resolution of  $4\text{ cm}^{-1}$  is recorded. A spectrum of acetonitrile is measured and used as background that is subtracted from the sample spectrum to yield the final transmission spectrum.

**C2.3 Electron impact (EI)-mass spectrometry:** Mass spectra (EI, 70 eV) were recorded with a Mass Selective Detector HP 6890 (*Hewlett Packard*).

**C2.4 High resolution mass spectrometry (HRMS)** were measured with a GCT Premier Micromass instrument (*Waters*).

**C2.5 Ultraviolet/visible light (UV/Vis)-spectra** were recorded in 1-centimeter quartz cuvettes with a Cary 100 Conc UV/Vis spectrophotometer (*Varian*).

**C2.6 Combustion analysis** were performed with a vario Micro cube (analytical laboratory, Technische Universität Kaiserslautern).

**C2.7 Melting points** [ $^{\circ}\text{C}$ ] were determined on a Koffler hot-plate melting point microscope

(*Reichert*) and are not corrected.

### C3 Reagents and Chromatography

**C3.1 Reagents:** Benzene, dimethyl formamide, dichloromethane, and diethyl ether were purified and dried according to standard procedures.<sup>[1]</sup> All other reagents were used as received from commercial suppliers (Sigma Aldrich, Acros Organics, Fisher Scientific, Merck), unless otherwise indicated. 3-Hydroxy-4-methylthiazole-2(3*H*)thione,<sup>[2]</sup> *N*-hydroxy-4-methylthiazole-2(3*H*)thione tetraethylammonium salt,<sup>[3]</sup> were prepared according to published procedures.

**C3.2 Thin layer chromatography:** Reaction progress was monitored via thin layer chromatography (tlc) on aluminum sheets coated with silica gel (60 F<sub>254</sub>, *Merck*). Compounds on developed TLC-sheets were detected with the aid of the UV-VIS indicator commercially disposed on the sheets, becoming apparent for example by a hand lamp emitting 254 nm light. As alternative method for detecting compounds, developed TLC-sheets were stained by Ekkert's reagent and subsequently heated, leading to blue-green spots for organobromines, blue spots for alcohols and yellow spots for alkoxyl radical precursors.

**C3.3 Column chromatography:** Column chromatography (flash chromatography) was performed using Geduran Si60 silica gel (40–63 µm) as stationary phase.

**C3.4 Gas chromatography coupled to mass spectrometry:** Mass spectra (EI, 70 eV) were recorded with a Mass Selective Detector HP 6890 (*Hewlett Packard*) connected to an Agilent-gaschromatograph.

## C4 Supplementary O-Alkyl Thiohydroxamate Chemistry

**C4.1 O-Pentyl 2-pyridylsulfenate (10c).** A solution of 1-pentoxypyridine-2(1H)-thione (376 mg, 1.91 mmol) was dissolved in deaerated perdeuterobenzene (4.0 mL) and placed into a water bath (18–20 °C). The reaction mixture is photolyzed for 15 min at 18–20 °C with 150 W tungsten light. A fraction of the solution is immediately analyzed by NMR-spectroscopy, showing resonances from 1-pentanol, pentanal, O-pentyl 2-pyridylsulfenate (**10c**), and 4-(pyridyl-2-sulfanyl)pentan-1-ol (**11**). *1-Pentanol*.  $^{13}\text{C}$  NMR ( $\text{C}_6\text{D}_6$ , 100 MHz)  $\delta$  14.3, 22.8, 28.1, 32.9, 62.6. *Pentanal*.  $^{13}\text{C}$  NMR ( $\text{C}_6\text{D}_6$ , 100 MHz)  $\delta$  13.8, 22.4, 24.2, 43.5, 200.9. 4-(pyridyl-2-sulfanyl)pentan-1-ol (**11**).<sup>[4]</sup>  $^1\text{H}$  NMR ( $\text{C}_6\text{D}_6$ , 400 MHz)  $\delta$  1.32 (d,  $J = 6.9$  Hz, 3 H), 1.42–1.52 (m, 2 H), 1.59–1.66 (m, 2 H), 2.71 (br s, 1 H), 3.57 (t,  $J = 5.3$  Hz, 2 H), 4.18 (sxt,  $J = 6.8$  Hz, 1 H), 6.37–6.40 (m, 1 H), 7.36 (dt,  $J_d = 8.1$ ,  $J_t = 1.0$  Hz, 1 H), 8.17 (ddd,  $J_d = 4.9$ , 1.9, 0.9 Hz, 1 H), 8.26 (ddd,  $J_d = 5.0$ , 1.8, 0.9 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{C}_6\text{D}_6$ , 100 MHz)  $\delta$  20.8, 30.1, 33.8, 38.7, 61.9, 119.1, 122.7, 135.8, 149.5, 160.2. For isolating O-pentyl 2-pyridylsulfenate (**10c**), the content of the NMR-tube was added to the rest of the reaction mixture, which was concentrated under reduced pressure. The remaining oil was purified by chromatography using a 1/1-mixture (v/v) of diethyl ether/pentane as eluent. *O-Pentyl 2-pyridylsulfenate (10c)*. Yield: 43%, colorless oil.  $R_f = 0.78$  [diethyl ether/pentane = 1:1 (v/v)].  $^1\text{H}$  NMR ( $\text{C}_6\text{D}_6$ , 400 MHz)  $\delta$  0.76–0.81 (m, 3 H), 1.10–1.18 (m, 4 H), 1.44–1.51 (m, 2H), 3.66 (t,  $J = 6.7$  Hz, 2 H), 6.38 (ddd,  $J_d = 7.4$ , 4.8, 1.1 Hz, 1 H), 7.03 (td,  $J_t = 7.8$ ,  $J_d = 1.8$  Hz, 1 H), 7.13 (dt,  $J_d = 8.1$ ,  $J_t = 0.9$  Hz, 1 H), 8.28–8.30 (ddd,  $J_d = 4.9$ , 1.8, 1.1 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{C}_6\text{D}_6$ , 100 MHz)  $\delta$  14.0, 22.6, 28.0, 30.4, 79.5, 116.0, 119.0, 136.3, 149.8, 166.0.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz)  $\delta$  0.88–0.94 (m, 3 H), 1.30–1.42 (m, 4 H), 1.71–1.78 (m, 2H), 3.94 (t,  $J = 6.7$  Hz, 2 H), 6.97 (ddd,  $J_d = 7.5$ , 4.9, 1.1 Hz, 1 H), 7.28 (dt,  $J_d = 8.1$ ,  $J_t = 0.9$  Hz, 1 H), 7.66 (td,  $J_t = 7.8$ ,  $J_d = 1.8$  Hz, 1 H), 8.44–8.46 (ddd,  $J_d = 4.8$ , 1.8, 0.9 Hz, 1 H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 100 MHz)  $\delta$  14.0, 22.4, 27.8, 30.1, 79.7, 116.2, 119.3, 136.8, 149.4, 165.0. Anal. Calcd. for  $\text{C}_{10}\text{H}_{15}\text{NOS}$  (197.27): C, 60.89; H, 7.66; N, 7.10; S, 16.25 Found: C, 60.64; H, 7.41; N, 7.02; S, 16.17.

When referenced versus the yield of isolated sulfenate **10c**, the yields of the remaining products observed via NMR-spectroscopy in the crude reaction mixture calculate as follows: 10% of 1-pentanol, 3% of pentanal, 43% of O-pentyl 2-pyridylsulfenate (**10c**), and 12% of 4-(pyridyl-2-sulfanyl)pentan-1-ol (**11**).

**C4.2 4-(Pyridyl-2-sulfanyl)pentan-1-ol (11).** A solution of 1-(1-pentoxypyridine-2(1*H*))thione (**4c**) (68.30 mg, 346  $\mu\text{mol}$ ) and deaerated perdeuterobenzene (0.7 mL) and photolyzed at 20 °C with 150 W-tungsten light for 5 minutes. The products are immediately analyzed by NMR-spectroscopy and purified by preparative thin layer chromatography using a 1/1-mixture of diethyl ether/pentane as eluent, to afford *O*-pentyl pyridine-2-sulfenate (**10c**) (51%;  $R_f$  = 0.78) and 4-(pyridyl-2-sulfanyl)pentan-1-ol (**11**) (32%;  $R_f$  = 0.35).

## C5 Supplementary Infrared Data of Thiohydroxamic Acids and *O*-Alkyl Thiohydroxamates

**C5.1 3-Hydroxy-5-(4-methoxyphenyl)-4-methylthiazole-2(3*H*)-thione (1a):** IR ( $\text{CCl}_4$ )  $\nu_{\text{max}}$  /  $\text{cm}^{-1}$  3006, 2960, 2838, 1514, 1361, 1292, 1274, 1253, 1178, 1146, 1038.

**C5.2 3-(*tert*-Butoxy)-5-(4-methoxyphenyl)-4-methylthiazole-2(3*H*)-thione (1b):** IR ( $\text{CCl}_4$ )  $\nu_{\text{max}}$  /  $\text{cm}^{-1}$  2981, 2935, 2838, 1605, 1510, 1464, 1441, 1393, 1381, 1371, 1333, 1294, 1271, 1251, 1177, 1133, 1037, 1030, 985. IR (MeCN)  $\nu_{\text{max}}$  /  $\text{cm}^{-1}$  2984, 2936, 2846, 1512, 1336, 1291, 1272, 1251, 1181, 1132, 1028, 988, 837.

**C5.3 3-Hydroxy-4-methylthiazole-2(3*H*)-thione (2a):** IR ( $\text{CCl}_4$ )  $\nu_{\text{max}}$  /  $\text{cm}^{-1}$  3125, 2969, 1508, 1440, 1360, 1302, 1188, 1142, 1023, 869.

**C5.4 1-Hydroxypyridin-2(1*H*)-thione (4a):** IR ( $\text{CCl}_4$ )  $\nu_{\text{max}}$  /  $\text{cm}^{-1}$  3115, 1612, 1563, 1485, 1456, 1414, 1265, 1193, 1171, 1141, 1076, 859, 834, 826.

## C6 Archive of Selected NMR-Spectra

**Figure C1.** Proton-1 NMR-spectrum of 3-(2-methylprop-2-ox-5-(4-methoxyphenyl)-4-methylthiazol-2(3H)-thione (**1b**) (400MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C2.** Carbon-13 NMR-spectrum of 3-(2-methylprop-2-ox-5-(4-methoxyphenyl)-4-methylthiazol-2(3H)-thione (**1b**) (150MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C3.** Proton-1 NMR-spectrum of 3-(2-methylprop-2-oxo)-4-methylthiazol-2(3H)-thione (**2b**) (400MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C4.** Carbon-13 NMR-spectrum of 3-(2-methylprop-2-oxo)-4-methylthiazol-2(3H)-thione (**2b**) (100MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C5.** Proton-1 NMR-spectrum of 3-(2-methylprop-2-oxo)-4-methyl-5-(4-nitrophenyl)thiazol-2(3H)-thione (**3b**) (400MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C6.** Carbon-13 NMR-spectrum of 3-(2-methylprop-2-oxo)-4-methyl-5-(4-nitrophenyl)thiazol-2(3H)-thione (**3b**) (100MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C7.** Proton-1 NMR-spectrum of a 83/17-mixture of 1-(2-methylprop-2-oxy)-pyridine-2(1*H*)-thione (**4b**) and *O*-(2-methylprop-2-yl)pyridine-2-sulfonate (**10b**) (600MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C8.** Enhancement of the proton-1 NMR-spectrum of a 83/17-mixture of 1-(2-methylprop-2-oxy)-pyridine-2(1*H*)-thione (**4b**) and *O*-(2-methylprop-2-yl)pyridine-2-sulfonate (**10b**) (600MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C9.** Carbon-13 NMR-spectrum of a 83/17-mixture of 1-(2-methylprop-2-oxy)-pyridine-2(1*H*)-thione (**4b**) and *O*-(2-methylprop-2-yl)pyridine-2-sulfenyl (**10b**) (150MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C10.** Proton-1 NMR-spectrum of a mixture of 2-(2-methylpropyl-2-sulfanyl)-5-(4-methoxyphenyl)-4-methylthiazole *N*-oxide (**6b**) (400MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C11.** Carbon-13 NMR-spectrum of a mixture of 2-(2-methylpropyl-2-sulfanyl)-5-(4-methoxyphenyl)-4-methylthiazole *N*-oxide (**6b**) (100MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C12.** Proton-1 NMR-spectrum of 2-(2-methylpropyl-2-sulfanyl)-4-methylthiazole *N*-oxide (**7b**) (600MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C13.** Carbon-13 NMR-spectrum of 2-(2-methylpropyl-2-sulfanyl)-4-methylthiazole *N*-oxide (**7b**) (150MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C14.** Proton-1 NMR-spectrum of 2-(2-methylpropyl-2-sulfanyl)-5-(4-nitrophenyl)-4-methylthiazole *N*-oxide (**8b**) (400MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C15.** Carbon-13 NMR-spectrum of 2-(2-methylpropyl-2-sulfanyl)-5-(4-nitrophenyl)-4-methylthiazole *N*-oxide (**8b**) (100MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C16.** Proton-1 NMR-spectrum of 2-(2-methylpropyl-2-sulfanyl)pyridine *N*-oxide (**9b**) (400MHz, CDCl<sub>3</sub>, 23 °C).

**Figure C17.** Carbon-13 NMR-spectrum of 2-(2-methylpropyl-2-sulfanyl)pyridine *N*-oxide (**9b**) (100MHz, CDCl<sub>3</sub>, 23 °C).

## C7 Computational Chemistry

### C7.1 Computational Details

Calculations were performed with the Gaussian03<sup>[5]</sup> suite of program, using density functional/Hartree-Fock hybrid models B3LYP and BHandHLYP, and Møller-Plesset second order perturbation theory MP2 in combination with the split valence double- $\zeta$  basis set 6-31+G(d,p). No symmetry or internal coordinate constraints were applied during energy function minimization. All energy function minimizations were conducted using ultrafine grid in combination with the tight option. Absence of an imaginary mode of vibration served as evidence for assigning computed structures as minimum on the potential energy surface. Approximate Gibbs free energies ( $G^{298.15}$ ) were obtained through thermochemical analysis for 298.15 K by unscaled frequency calculation from the thermal correction reported by Gaussian03. Likewise obtained Gibbs free energies take into account zero-point correction, thermal correction, and entropy. All transition structures were maxima on electronic potential energy hypersurface, which may not correspond to maxima on the free energy surface.

All NBO-calculations<sup>[6]</sup> were performed with the density functional/Hartree-Fock hybrid model B3LYP and split valence double- $\zeta$  basis sets 6-31G(d) using input coordinates from B3LYP/6-31+G(d,p)-energy minimized structures.

Vibrational analysis of 3-(*tert*-butoxy)thiazolethiones were performed from B3LYP-energy-minimized structures, considering corrections from Grimme (D3 dispersion parameters), and using the TZVP-basis set. For energy minimizing structures we used the Berny algorithm implemented in GAUSSIAN, and energies and gradients from TURBOMOLE, for shortening computing time. Computed harmonic vibrational frequencies were scaled by factor 0.99, since calculated vibrational frequencies disregarding anharmonicities generally are larger than experimental values. For comparing computed to experimental spectra, we transformed line spectra using Lorentzian-functions with full width at half maximum (FWHM) of 15 cm<sup>-1</sup> into simulated spectra.

## C7.2 Ball-and-Stick Presentations of Computed Structures

Graphics displaying computed equilibrium structures in the succeeding sections were generated from B3LYP-calculated atomic coordinates, which were file-converted with OpenBabel<sup>[7]</sup> for generating presentation graphics with ChemPlus-add on (release 1.6) for HyperChem 4.5<sup>[8]</sup> MP2-calculated geometries differed insignificantly with respect to bond lengths, bond angles and torsion angles, but showed similar conformations for energy-minimized structures and therefore were presented separately. In succeeding depictions of modelled compounds, oxygen is displayed in red, carbon in gray, nitrogen in blue, sulfur in yellow, and hydrogen in white.

### C7.3 3-(*tert*-Butoxy)-4-methylthiazole-2(3*H*)thione (2b)

Figure C36. Computed minimum structure of 3-(*tert*-butoxy)thiazolethione **2b**.

## C8 Vibrational Analysis

### C8.1 General remarks

For assigning N,O- and C=S-vibrations, harmonic frequencies of isotopomeric compounds were computed starting from atomic coordinates of B3LYP/6-31+G\*\*- and B3LYP/TZVP-energy minimized structures.<sup>[5]</sup> Isotopes considered are the following pairs: C<sup>12</sup>/C<sup>13</sup>, N<sup>14</sup>/N<sup>15</sup>, O<sup>16</sup>/O<sup>18</sup> and S<sup>32</sup>/S<sup>34</sup>. Vibrational modes were characterized from animations using the program Molden.<sup>[11]</sup>

### C8.2 Hydroxylamine

<sup>14</sup> <sup>16</sup> H <sub>2</sub> N—OH	<sup>15</sup> <sup>16</sup> H <sub>2</sub> N—OH	<sup>14</sup> <sup>18</sup> H <sub>2</sub> N—OH
$\tilde{\nu}_{\text{N,O}} = 929 \text{ cm}^{-1}$	$912 \text{ cm}^{-1}$	$908 \text{ cm}^{-1}$
	$(-17 \text{ cm}^{-1})$	$(-21 \text{ cm}^{-1})$

**Figure C60.** Calculated (B3LYP/6-31+G\*\*) wavenumbers for the nitrogen-oxygen stretching mode of hydroxylamine.

### C8.3 Thioformaldehyde

<sup>32</sup> S H <sup>12</sup> H	<sup>32</sup> S H <sup>13</sup> H	<sup>34</sup> S H <sup>12</sup> H
$\tilde{\nu}_{\text{C,S}} = 1081 \text{ cm}^{-1}$	$1057 \text{ cm}^{-1}$	$1071 \text{ cm}^{-1}$
	$(-24 \text{ cm}^{-1})$	$(-10 \text{ cm}^{-1})$

**Figure C61.** Calculated (B3LYP/6-31+G\*\*) wavenumbers for the nitrogen-oxygen stretching mode of hydroxylamine.

**Abstract:** *O*-Alkyl thiohydroxamates are useful compounds to serve as alkoxy radical precursors in organic chemistry. Synthesis of primary and secondary derivatives thereof are already established<sup>[1]</sup>, while preparation of the corresponding *tert*-alkoxy thiohydroxamates remained difficult. Using the isourea-method preparation of 3-(*tert*-alkoxy)-thiazole-2(3H)-thiones was verified from 3-hydroxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione (MANTTOH), *tert*-alcohols, diisopropylcarbodiimide (DIC), and copper(I)-chloride under nonoxidative, pH-neutral conditions. Radical precursor formation was feasible in up to 64 % yield. On activation, the molecules liberated *tert*-alkoxy radicals, which were investigated in mechanistic studies to determine rate constants of (a) radical substitution, (b) intramolecular and (c) intermolecular addition. For the first time 2,2,5-substituted tetrahydrofurans and 2-bromo-3-alkoxynorbornanes were isolated via an alkoxy radical route leading to unexpected and synthetically useful selectivities as outlined in this contribution.<sup>[2]</sup>

## Background

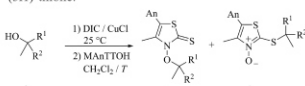

*tert*-Alkoxy radicals undergo fast uni- and bimolecular reactions to leave diagnostic product mixtures. Chemical changes thereby follow distinct patterns of homolytic substitution,  $\beta$ -C-C-homolysis, and  $\pi$ -bond addition, to mention the most important elementary reactions.<sup>[3]</sup> This combination of reactivity and selectivity explains the significance that *tert*-alkoxy radicals have gained for elucidating reaction mechanisms in physical organic chemistry<sup>[4]</sup>, atmospheric science<sup>[5]</sup>, biochemistry<sup>[6]</sup> and macromolecular chemistry<sup>[7]</sup>.

## Conclusions

*O*-Alkyl isoureas are surprisingly selective reagents to convert thiohydroxamic acids into derived *O*-alkyl esters. The latter compounds, in this study, were successfully applied to generate *tert*-alkoxy radicals for synthesis of 2,2,5-substituted tetrahydrofurans and 2-bromo-3-alkoxynorbornanes. The study also shows that chemical reactivity of *tert*-alkoxy radicals is similar to their secondary and primary congener, in spite of higher steric encroachment in proximity of the *O*-radical center.

# Tertiary alkoxy radicals from 3-alkoxythiazole-2(3H)-thiones

Christine Schur, Nina Becker, Uwe Bergsträßer, Jens Hartung\*

Department of Organic Chemistry, Technische Universität Kaiserslautern, Erwin-Schrödinger-Straße, 67663 Kaiserslautern, Germany

## Abstract

Since generation of *tert*-alkoxy radicals under nonoxidative, pH-neutral conditions remained difficult, we developed in this project a practical method for synthesis of 3-(*tert*-alkoxy)-thiazole-2(3H)-thiones from 3-hydroxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione (MANTHO), selected *tert*-alcohols, diisopropylcarbodiimide (DIC) and copper (I) chloride. Radical precursor formation was feasible in up to 64 % yield. If activated, the molecules liberate *tert*-alkoxy radicals, which were applied in mechanistic studies to determine rate constants of (a) radical substitution (1,5-H-atom shift), (b) intramolecular and (c) intermolecular addition. These reactions represent key steps in synthesis of 2,2,5-substituted tetrahydrofurans and 2-bromo-3-alkoxybicyclo[2.2.1]heptanes.

## Background

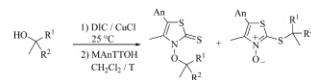

*tert*-Alkoxy radicals undergo fast uni- and bimolecular reactions to leave diagnostic product mixtures. Chemical changes thereby follow distinct patterns of homolytic substitution,  $\beta$ -C-C-homolysis, and  $\pi$ -bond addition, to mention the most important elementary reactions.<sup>[2]</sup> This combination of reactivity and selectivity explains the significance that *tert*-alkoxy radicals have gained for elucidating reaction mechanisms in physical organic chemistry<sup>[3]</sup>, atmospheric science<sup>[4]</sup>, biochemistry<sup>[5]</sup> and macromolecular chemistry.<sup>[6]</sup>

## Conclusion

By means of using the isourea pathway, it was for the first time possible to obtain *tert*-alkoxy radical precursors from thiohydroxamic acids. These compounds were successfully converted in radical substitutions as well as additions, to get 2,2,5-substituted tetrahydrofurans and 2-bromo-3-alkoxynorbornanes. Especially intermolecular addition becomes more and more important, as the knowledge about this reaction increases.

Rate constants, from the mechanistic part of the study, show that *tert*-alkyl substitution near oxygen does not reduce alkoxy radical reactivity, at least in the investigated cases.

# Annulated and Bridged Tetrahydrofurans from Alkenoxyl Radical Cyclization

Christine Schur<sup>a</sup>, Jens Hartung<sup>a,\*</sup><sup>a</sup> Fachbereich Chemie, Organische Chemie, Technische Universität Kaiserslautern, Erwin-Schrödinger-Straße, D-67663 Kaiserslautern, Germany

## Abstract

Cycloalkyl-annulated and bridged 4-penten-1-oxyl radicals cyclize stereoselectively in solutions of bromotrichloromethane to obtain tetrahydrofuran-derived bicyclic and tricyclic  $\beta$ -bromohydrin ethers in up to 95 % yield. Stereocontrol in synthesis of bicyclic tetrahydrofurans thereby arises from steric substituent effects, becoming more effective as the distance of the substituents to the C,C-double bond shortens. Endocyclic double bonds are intramolecularly attacked by the oxygen radical from the direction where the side chain is attached to the alicyclic subunit. Model calculations on a density functional level of theory show that the intrinsic barrier, reflecting strain effects in 5-*exo*-additions, is similar for 2,3-*cis*-cyclization of the 2-(cyclohexen-3-yl)ethyloxy radical and the 4-penten-1-oxyl radical. The results of the calculation were exemplified in synthesis of a diastereomerically pure tricyclic brominated tetrahydrofuran from a verbenylethyloxy radical.

## Background

Cyclization reactions of 4-penten-1-oxyl radicals, generated from thiohydroxamate derived radical precursors, are well known in current literature.<sup>[1,2]</sup> Selectivities of products gained from these compounds follow systematic patterns depending on substituent effects as described below. In position 1 or 3 substituted 4-pentenoxyl radicals, with exception of 1-aryl-substituted compounds, preferentially cyclize 5-*exo*-trans selectiv, whereas substituents in position 2 predominantly provide *cis*-substituted tetrahydrofurans. Regioselectivity is changed by substituents in position 4. In this case the 6-*endo*-trig cyclizations, especially for phenyl groups. Alkyl- and aryl-groups in position 5 increase reactivity and selectivity of 5-*exo*-trig cyclizations, in doing so the effect of two substituents is higher than the effect of one. To explore new aspects of stereocontrol in intramolecular alkenoxyl-radical addition reactions of more complex structures than monocyclic tetrahydrofurans, we investigated in this study stereochemical guidelines for synthesis of bicyclic and tricyclic tetrahydrofuran derived compounds. The basic structures investigated are type A-C cycloalkyl-annulated 4-pentenoxyl radicals and type D and E cycloalkenylalkoxy radicals.

## Chain reaction for intramolecular addition

Conditions (cond.): (i) hv/25°C; (ii) AIBN/80°C

## Results and Conclusion

stereoselectivity **correlates** with 4-penten-1-oxyl radical cyclization

stereoselectivity **differs** from 4-penten-1-oxyl radical cyclization

induction (main product ratio):  
(++) very high (85–99)  
(+) high (75–84)  
(-) low (<75)

major inductor for types A–C

major inductor for types D and E

MTOR =

For simplification, atom count refers in all cases to alkoxy radical convention and not to heterocycle convention for cyclic compounds.

## Danksagung

Meinen ersten Dank möchte ich an Prof. Dr. *Jens Hartung* richten, der mich sehr herzlich in seinem Arbeitskreis aufgenommen und während der gesamten Promotion bei wissenschaftlichen Fragestellungen, der Anfertigung von Manuskripten, Postern, Buchbeiträgen und der vorliegenden Doktorarbeit stets unterstützt hat. Ohne sein Engagement hätten diese Werke nie die Form erlangt, in der sie heute vorliegen. *Vielen Dank!*

Dem gesamten Arbeitskreis danke ich für die gute Stimmung, Hilfsbereitschaft, für viele hilfreiche Diskussionen, chemischer und nicht-chemischer Natur, sowie für schöne Aktivitäten nach Laborende. Insbesondere danke ich dabei *Georg* für die Einführung der heute noch existierenden und über Promotionen hinaus geltenden Wurstmarkt-Tradition, sowie für meine ersten Erfahrungen mit dem „Betzen“...ich weiß, es heißt „Betze“!!! *Domi* danke ich für den Präfix „Mega“ und *Barbara* für den wohl lustigsten Diskussionsauftakt einer Promotion. *Heiko* danke ich für all seine „todesgeilen“ Gründe gemeinsam ein Fläschchen Sekt zu köpfen und *Mario* für seine ansteckend ruhige und sehr angenehme Art. Meinen Thizolthion-„Eltern“ *Nina* und *Andreas* danke ich für all die hilfreichen Tipps und Tricks rund um Thiohydroxamsäuren und *Andreas* darüber hinaus für die sehr angenehme und freundliche Betreuung meines ersten FPs. *Olli* danke ich für seinen alljährlichen „Rückblick“, seine wertvollen Hilfestellungen und natürlich das übelst geile Handballspiel.

*Irina* danke ich für viele schöne Stunden im Labor, die zahlreichen Lästereien und die unzähligen Taxi-Dienste. Nicht zu vergessen die massenhaften NMR-Messungen und die gemeinsamen Nächte in der „Vilsmaier-Residenz“. *Diana* danke ich für ihre mehr als aufmunternde Art Leistungen Studierender in Klausuren zu bewerten und *Patrick* für die „Einladung“ zur Mikrowellentagung nach Düsseldorf, sowie der Auffrischung meiner russisch Kenntnisse. *Matthias* danke ich für die Beantwortung jeder(!) Frage, sowie für jegliche Art von technischer Unterstützung an PC und Auto.

Auch *Maike* möchte ich für viele, viele Kutschierfahrten und NMR-Messungen danken, aber insbesondere für ihr strahlendes Lächeln und ihre liebenswürdige Art, die selbst bei übelster Laune aufmunternd wirkt. *Madlen* danke ich für die Überprüfung jeder „Milchmädchenrechnung“ und die „Audienz im fernen Osten“. *Alexander H.* danke ich für seine konstruktive Kritik und fachliche Bewertung chemischer Fragestellungen sowie für viele schnelle Korrekturen. Den tatkräftigen Nachfolgern der Radikal-Szene *Alexander K.*,

*Benny, Swen, Britta und Katharina* danke ich für die Unterstützung und Diskussionsbereitschaft bei neuen Thiazolthion-Herausforderungen. *Alexandra* danke ich für ihren absolut unkomplizierten und coolen Charakter! *Melanie* danke ich für die bereitwillige Übernahme all meiner Dienste und *Mark* für seine offene Art, die zum Vorschein kommt sobald man ihn angesprochen hat.

*Luki und Jürgen* danke ich für die Teilnahme an der morgendlichen Kaffepause und dem damit verbundenen frischen Wind in Kombination mit äußerst interessanten Frühstücksgewohnheiten (@ Luki). *Frank* danke ich für den stets charmanten Empfang in der Chemikalienausgabe und für das zügige Erfüllen zahlreicher technischer Wünsche. Den Mitgliedern der Analytik-Abteilung *Birgitt, Ruth, E. Biehl, Jana* und *Patrick* danke ich für unzählige CHN- und HRMS-Messungen, sowie für diverse Tipps und die Leihgabe analytischer Instrumente. *Uwe* danke ich für Hilfe jeglicher Art. Angefangen von Kristallstruktur- oder HRMS-Messungen und deren Auswertungen, für Literaturrecherchen, Synthesetipps aber auch für die Organisation von Wandertagen, die Beteiligung am Praktikum und und und.....Uwe du bist einfach unser „Mädchen für Alles“ und wir danken dir viel zu selten dafür. *Vielen, vielen lieben Dank !!!!!* Ein Dank für bürokratische und organisatorische Erledigungen geht an *Edith* und *Susanne*.

Meinen Praktikantinnen und Praktikanten *Alexander Ganß, Julia Becker, Patrick Unger, Jennifer Mohrbach* und *Benjamin Erb* danke ich für die Beiträge die sie zu meiner Forschung geleistet haben. Für spezifische Messungen danke ich *Dr. Harald Kelm* (NMR / X-Ray), *Christiane Müller* (NMR), *Dr. Reinhard Philipp* (ESR) und *Manuel Zimmer* (FTIR).

Der wichtigste Dank gilt meinen Eltern, Schwestern und Philip! Ich danke euch von ganzem Herzen für eure unendliche Unterstützung während der gesamten Promotion, für grenzenloses Zuhören, Trösten, Motivieren und Aufmuntern, aber insbesondere dafür, dass Ihr mir immer das Gefühl gegeben habt euch niemals enttäuschen zu können. **Danke!!!**

# Lebenslauf

Christine Schur

## Ausbildung

02.2009–05.2015

### Promotion

TU Kaiserslautern/ Fachbereich Organische Chemie

Betreuer: Prof. Dr.-Ing. Jens Hartung

Titel der Dissertation: Reaktivität und Selektivität  
anellierter, verbrückter und tertiärer Sauerstoffradikale

Promotion mit der Gesamtnote: „sehr gut“

10.2003–12.2008

### Diplom-Chemiestudium

TU Kaiserslautern/ Fachbereich Organische Chemie

Diplomarbeit in der Gruppe von Prof. Dr.-Ing. Jens Hartung

Titel der Diplomarbeit: Synthese *O*-Alkyl- und *O*-Acyl-  
substituierter Thiohydroxamsäuren zur Untersuchung neuer  
Selektivitäten in Sauerstoffradikalreaktionen

Diplom mit der Gesamtnote: „sehr gut“

08.2007–09.2007

### Forschungspraktika

Synthese eines Cyclohexapeptidtrithiols

Arbeitsgruppe von Prof. Dr. Stefan Kubik

01.2007–02.2007

Synthese und Evaluierung des Radikalvorläufers 3-Hydroxy-4-  
methyl-5-(4-acetimidophenyl)thiazol-2(3*H*)-thion

Arbeitsgruppe von Prof. Dr.-Ing. Jens Hartung

11.2006 (3 Wochen)

### Wahlfachpraktikum

Synthese von 5-Carboxyindirubin und Umsetzung zu Indirubin-5-  
carbonsäurepentafluorphenylester

Arbeitsgruppe von Prof. Dr. med., Dr. rer. nat. Dieter Schrenk

## Schulbildung

02.1995–03.2003

Integrierte Gesamtschule Rockenhausen  
Abitur mit der Gesamtnote: „gut“  
Leistungskurse: Gesundheit, Biologie, Englisch

09.1994–02.1995

Integrierte Gesamtschule Kaiserslautern  
Bertha von Suttner

# Veröffentlichungen

## Übersichtsartikel

- *Annulated and Bridged Tetrahydrofurans from Alkenoxyl Radical Cyclization.* C. Schur, H. Kelm., T. Gottwald, A. Ludwig, R. Kneuer, J. Hartung, *Org. Biomol. Chem.* **2014**, 12, 8288–8307.
- *Discussion Addendum for: N-Hydroxy-4-(p-chlorophenyl)thiazole-2(3H)-thione.* C. Schur, I. Kempter, J. Hartung, *Org. Synth.* **2012**, 89, 409–419.
- *Tertiary Alkoxy Radicals from 3-Alkoxythiazole-2(3H)-thiones.* C. Schur, N. Becker, U. Bergsträßer, T. Gottwald, J. Hartung, *Tetrahedron* **2011**, 67, 2338–2347.
- *Efficiency of alkoxy radical product formation from 5-substituted 3-alkoxy-4-methylthiazole-2(3H)-thiones.* J. Hartung, C. Schur, I. Kempter, T. Gottwald, *Tetrahedron* **2010**, 66, 1365–1374.
- *A Practical Method for O-Acylation of N-Hydroxythiazole-2(3H)-thiones.* C. Schur, A. Groß, J. Hartung, *Synthesis* **2010**, 3, 538–542.
- *Hindered rotation in N-acyloxy-4-methylthiazole-2(3H)-thiones.* J. Hartung, C. Schur, I. Kempter, S. Altermann, G. Stapf, U. Bergsträßer, T. Gottwald, M. Heubes, *Tetrahedron* **2009**, 65, 7527–7532.

## Buchbeitrag

- *Propylphosphonic Anhydride.* C. Millbanks, M. Bonnekessel, C. Schur, J. Hartung, *e-EROS Encyclopedia of Reagents for Organic Synthesis*, **2012**, Wiley VCH.

## Patent

- *Tageslichtaktive Substanzen zur Vermittlung von Polymerisationsreaktionen.* H. Ritter, G. Maatz, J. Hartung, C. Schur, **2009**, PCT/EP2009/006617.

## Posterpräsentationen

- Annulated and Bridged Tetrahydrofurans from Alkenoxyl Radical Cyclization
  - *GDCh-Wissenschaftsforum Chemie* **2013**, Darmstadt
  
- Tertiary Alkoxy Radicals from 3-Alkoxythiazole-2(3*H*)thiones
  - *ISOFR-11*, **2012**, Bern, Schweiz und
  - *GDCh-Wissenschaftsforum Chemie* **2011**, Bremen
